Blood Groups in Cyprus.—While establishing a blood bank in Cyprus, Clearkin made blood tests on 10,000 of the population of the island (*Brit. M. J.* 2:939, 1958). He examined the distribution of ABO and Rh (D) blood groups among both the Greek-speaking and Turkish-speaking inhabitants of the island. Basing his conclusions on fully adequate population samples, he found little difference between the ABO and Rh (D) blood group distributions in the two groups, but in their ABO frequencies both groups differed from the Greeks on the European mainland, and resembled more closely the Turks and inhabitants of the Levant. Populations which within the last few thousand years have shared a common ancestry have similar blood group frequencies. Hence a difference in blood group frequencies is evidence that ancestries differ. It is thus surprising to learn that the Greek-speaking Cypriots do not appear to have Greek ancestry at all, and are in fact genetically more closely related to the Turkish Cypriots than to the Greeks. Whether these observations on blood groups will help solve the racial problem in Cyprus is another matter.

Work Study in Hospitals.—Work study and scientific methods of working are to be tried in the physiotherapy departments of 3,000 hospitals in the

National Health Service. Because these are among the busiest departments in most hospitals, and are so short staffed, it is hoped that work studies may increase efficiency. More than 100 heads of physiotherapy departments have just attended a conference at Westminster Hospital, London, to deal with the problem. Work study methods are already in use in many departments at this hospital.

Addiction to Freely Obtainable Drugs.—All drugs which it is thought can cause, or are likely to cause, addiction are obtainable only on a doctor's prescription. According to the World Health Organization committee on drug addiction, such addiction is a state of periodic or chronic intoxication, detrimental to the individual and to society, produced by the repeated use of a drug. The characteristics of addiction are an overpowering desire to take the drug and eagerness to obtain it by any means, a tendency to increase the dose, and a psychological and sometimes physical dependence on it. The sale of new drugs may escape being restricted, as they may be in use for some time before their addictive properties are discovered. Drugs that have either a euphoriant or sedative action are likely to cause addiction in predisposed persons. Three drugs obtainable in Britain without prescription have recently been reported to have addictive properties. They are carbromal, tincture of chloroform and morphine (Chlorodyne), and phenmetrazine. Carbromal, a mild hypnotic and sedative, is sold by pharmacists under a number of proprietary names or as a constituent of proprietary mixtures. Some patients who are advised to take one or two tablets containing carbromal daily eventually take 15 to 20. Addicts taking it may become stuporous and ataxic. Chlorodyne, which contains 1 mg. of morphine in a two-teaspoon dose, has long been used as a domestic remedy. Its use in Britain is unrestricted. A case has been reported in which the patient consumed 160 ml., or one-third of an ounce, of this tincture daily. This amount contains 16 mg. of morphine. Phenmetrazine is a weight-reducing drug that is being used by addicts in place of amphetamine, a restricted drug, although its euphoriant properties are not so great. It is suggested that all new drugs should be initially listed under the poisons rules until they are shown to be innocuous, at which time they may be released and obtained without prescription.

Anastomosis in the Coronary Circulation.—It is generally believed that in the coronary circulation anastomoses follow the occurrence of ischemic myocardial episodes, appearing where and when needed. This view is questioned by Laurie and Woods, who investigated the blood supply in both normal and diseased hearts of 150 Bantu patients (*Lancet* 2:812, 1958). Working in a native reservation they were able to perform autopsies on 67% of the patients dying in hospital. Hearts were perfused after death with lead phosphate suspended in gelatin, and roentgenograms were taken of the coronary circulation. The coronary artery and its major vessels were examined microscopically. Of 200 such perfusions, only 150 were technically successful. Functionally significant anastomoses were found in 75% of normal hearts from patients over 4 years of age, but in only 23% of hearts from patients with chronic ischemic heart disease. Functionally significant anastomoses were found even in the hearts of some newborn infants with no cardiac disorder. One child 13 days of age had a complete anastomosis to the left circumflex artery and to the whole right side of the heart, shown by perfusion into the left descending coronary artery. The authors considered that if anastomoses form after an ischemic heart attack, as has been suggested, there would be insufficient time for these to develop, as the myocardium cannot survive more than 20 minutes if deprived of its blood supply. They believed that the most likely explanation is that most healthy persons have a functionally important coronary anastomotic blood supply at birth. This anastomosis probably protects some against ischemic heart disease and may modify this condition in others.

Reduction of Sputum Viscosity.—In chronic bronchitis the mucosa of the bronchial tree is abnormal and the mucus-secreting glands, which are overdeveloped, produce excessive amounts of an abnormally tenacious mucus. This is a good medium for bacterial growth and leads to superadded infection and purulent sputum. The viscosity of the sputum of the chronic bronchitic is proportional to its hydration and mucoprotein content. The latter consists largely of desoxyribonucleoprotein (DNP) fibers. Robinson and co-workers (*Brit. M. J.* 2:119, 1958) showed that the viscosity of bronchitic sputum can be reduced, and the clinical condition of the patient improved, by the insufflation into the peribronchial tree of a dry powder containing desoxyribonuclease and chymotrypsin. The size of the particles is important because if they are too large they will not reach the peripheral bronchial tree and may be deposited in the pharynx and trachea. The ideal particle size is around 3μ. With use of fluorescent-labeled chymotrypsin it was shown by means of bronchoscopy that some of the particles reached the terminal bronchioles. Tests were made with the powder on 36 chronic bronchitics. The sputum was collected daily, measured, and examined for mucoprotein and DNP fibrils, color, consistency, and relative viscosity. In 86% of the patients the sputum showed decreased viscosity, and in 66% there was appreciable lysis of the DNP fibrils. In 67% there was subjective improvement, which was pronounced in several. Sputum was expectorated more readily and physical signs, particularly dyspnea, improved in nearly 50%. The possibility of sensitization to the enzymes exists but appears to be remote.

Health Hazard from High-Power Radio Stations.—*The Times* reported that the operation of certain forward-scatter radio links to be set up in Britain under NATO arrangements may constitute a hazard to the health of the local community. Each of these high-power, two-way directional radio stations would have a sterilized zone in its beam extending a mile or so ahead of the station in the direction of the transmission. The public will not be allowed permanently in these zones, and any existing farms or homes in the immediate vicinity of the new radio stations would have to be evacuated. It is even suggested that "death rays" might be emitted in these new radio stations. The Ministry of Defense, on the other hand, minimized the danger and stated that there might be a slight radiation hazard from the introduction of new radio techniques and advised the fencing off of an area of about 40 yd. in depth in front of the transmitter cones. The matter is being taken up by the Medical Research Council, whose experts pointed out that the hazards are not as great as those of nuclear radiation. The energy emitted does not produce the same biological changes and as far as is known does not have any genetic effects on future generations. The Council stated that those who have been working with radar for nearly 20 years have not suffered from any ill-effects and that animal experiments show that this form of radiation must be of high potential to constitute a hazard to health.

Cytological Screening for Cancer of the Cervix.—A report from the Faculty of the College of General Practitioners of S. E. Scotland shows that the cytological detection of early cervical carcinoma can be readily undertaken in general practice, and that it is well worth while in view of the number of unsuspected cases of cancer brought to light. Twenty general practitioners took cervical smears from all women coming for postnatal examination, from postmenopausal women without a history of disease of the genital organs, and from as many women as possible in whom a complete medical examination was indicated. Cervical smears were taken from 1,000 women and the slides sent to Edinburgh University for pathological examination. There were 15 unsuspected positives; that is, those who had a healthy cervix on inspection and palpation, but whose cervical smear was either suspected of cancer or frankly malignant. Five atypical cases were also found. The average age of this group was 35½ years. These patients were immediately referred to a gynecologist for further treatment. Six underwent total hysterectomy, one was treated with radium, and the rest were still under observation, four of them having had the cervix amputated. This incidence of 1.5% unsuspected cases of cancer of the cervix detected in general practice was high. Figures from hospital surveys made in gynecologic departments were about half this. The general practitioners concerned were unanimous in their opinion of the value of the cervical smear as a routine screening test and considered that it should be part of every pelvic examination.

Cutting Health Service Costs.—Proposals for improving the National Health Service without increasing the cost were made in the first of a series of debates at the Local Government Conference in response to a paper by Sir Keith Joseph, M. P. Sir Keith referred to defects in the service and recommended that before going to the taxpayer for extra revenue, efforts be made to improve efficiency by modern management techniques. Specifying the drug bill in particular, he said that 10% of the total cost went for drugs and that a method should be found to make the public pay more of this cost. A false incentive was given by the relatively low charge of 14¢ for prescriptions when the prescribing cost alone was nearly 28¢. The charge must, however, be so arranged that it does not discourage recourse to the physician when necessary. The grievances of patients who wait hours at clinics to see a consultant for a few minutes were aired by Mr. P. Maybury, of Swansea, who said the consultants are not to blame as many are overworked. The system falls down for lack of coordination. Dr. Dulcie Staveley, herself a consultant who kept patients waiting, blamed the general public's lack of a sense of time, saying, "You can give them appointments and work out the average amount of time it takes to see them but you can't work out whether the average person will keep the appointment." Mr. W. Lindsay, vice-chairman of the East Sussex County Council, complained that benefits are given to people who do not need them. The patient should at least pay for his board and lodging in the hospital if he can afford to do so.

Mr. Walker-Smith, Minister of Health, described the service as generally efficient although methods of promoting efficiency are always being considered. When the Labor Government was in office not one hospital was in progress or planned. Today 10 are in progress and 11 planned; 31 major schemes of hospital extension and modernization are in progress, and 60 are planned. Regarding patients' waiting time the Minister said that a hospital could never be equated with a factory or the healing of the sick with the making of goods, but new techniques would be introduced where it was possible without detriment to the care and treatment of the sick. Five times as much is spent on drugs to keep patients out of hospitals as on drugs in hospitals. This gives a double benefit. This does not mean that costs should not be curtailed as far as possible without detriment to the patient. The speed and stress of modern life has increased the ratio of mental to physical illness. More than 40% of the hospital beds are devoted to mental cases. This is a great problem and challenge. More of these patients should be treated in the community rather than the hospital. Old people must be helped not only to live longer but to remain fit and active. Greater emphasis must also be placed on the prevention of illness.

At a Conservative Party conference Mr. Thompson, Parliamentary Secretary, Ministry of Health, stated that the big economies people want in the Health Service can be made only by closing hospital beds, charging for doctors' visits, or scrapping important parts of the service. Those who urge a better service at lower cost should not ask for the impossible. He was replying to a motion which urged that, in view of the ever-increasing rise in Health Service cost, the efficiency of the service be investigated. Mrs. J. Adams said the greatest resentment was directed at the foreign nationals and others who do not need a passport to come here and reap the benefits of the service. She had found that nationals from 15 foreign countries had obtained help in one year. Mr. F. A. Tomlinson claimed that in the vacation months an ever-increasing number of so-called working men went sick and drew $28 from the National Health Service in addition to their regular pay. An ever-growing number also imposed on the service through bulk compensation for industrial injury.

Center for Spastics.—The only training center in the world set up especially to train spastics for work in industry was officially opened at Welwyn, Hertfordshire, about 18 months ago. Since its opening it has fitted 20 young men and women, at one stage thought to be untrainable, for industrial jobs. In the workshop carpentry, light engineering, printing, and other technical subjects are taught. The center has accommodations for 32 spastics between the ages of 16 and 25, and there is a long waiting list. When students arrive, many of them cannot read or write, and all have physical disabilities which make the simplest process a heavy task. As well as being taught the skills for "outside" jobs, they have to be taught how to live. Many have got into the habit of lying in bed for most of the day. Frequently there is nothing else for them to do, and they are in the way of other members of their families if they get up. The strict schedule of the center (set times for meals, work, and learning) gives them their first idea of normal working life. In many cases they are given their first hope of being able to take part in that life. Finding jobs for the trained students is the biggest problem and slows down the work of the center. Employers are sympathetic but wary and fellow workers are apprehensive at first. The man in the street is too often ignorant even of what spastic means. There have been a few total failures, but after 18 months this center has established itself as a realistic training ground doing a sound and valuable job.

Alcohol and Driving.—Drew and co-workers examined the effect of small doses of alcohol on driving skill (*Brit. M. J.* 2:993, 1958). The apparatus used was a "Miles motor driving trainer," in which the subject sits in a dummy car facing a translucent screen in a darkened room. Behind the screen is a perspex disk with a road scene painted on it and this is projected, very much magnified, on the screen by a lamp. As the driver operates the accelerator and steering wheel the car appears to progress along the road. The apparatus used gives the illusion of driving along a mile of road. The aspects of performance scored were accuray of tracking, speed of driving, and the control movements of steering wheel, accelerator, brake, clutch, and gear lever. Records were also made of the number of collisions with the side of the road that would be likely to happen under normal driving conditions. The subjects tested, 40 volunteers from the staff of the Road Research Laboratory ranging in age from 23 to 40 years, were given a 20% solution of alcohol flavored to disguise the alcohol content. The dose ranged from 0.2 to 0.65 Gm. of alcohol per kilogram of body weight. The alcohol level was determined in the blood, urine, and breath at intervals over a period of two and one-half hours. The peak blood alcohol concentrations from the doses given were about 20, 40, 60, and 80 mg. per 100 ml. and the ratio of urine alcohol to blood alcohol was 1.25 to 1. The best results with breath testing apparatus were obtained with one known as the "breathalyser," which gave values corresponding closely to the blood alcohol values. The other forms of apparatus either showed high constant errors or were difficult to use.

Performance began to deteriorate with blood alcohol concentrations of the order of 20 to 30 mg. of alcohol per 100 ml., corresponding to an intake of 0.2 to 0.3 Gm. per kilogram of body weight. The deterioration was progressive and linearly related to blood alcohol level. There was no evidence of a threshold effect. The impairment in performance was shown most clearly in the operation of the controls, particularly in the timing of steering wheel movements. Mean error showed an increase with an increase in blood alcohol, amounting to about 16% deterioration with a blood alcohol concentration of 80 mg. per 100 ml. Part of the increase in error was due to a significant tendency which was pronounced in several. Sputum was expectorated more readily and physical signs, particularly dyspnea, improved in nearly 50%. The possibility of sensitization to the enzymes exists but appears to be remote.

Health Hazard from High-Power Radio Stations.—*The Times* reported that the operation of certain forward-scatter radio links to be set up in Britain under NATO arrangements may constitute a hazard to the health of the local community. Each of these high-power, two-way directional radio stations would have a sterilized zone in its beam extending a mile or so ahead of the station in the direction of the transmission. The public will not be allowed permanently in these zones, and any existing farms or homes in the immediate vicinity of the new radio stations would have to be evacuated. It is even suggested that "death rays" might be emitted in these new radio stations. The Ministry of Defense, on the other hand, minimized the danger and stated that there might be a slight radiation hazard from the introduction of new radio techniques and advised the fencing off of an area of about 40 yd. in depth in front of the transmitter cones. The matter is being taken up by the Medical Research Council, whose experts pointed out that the hazards are not as great as those of nuclear radiation. Center for Spastics.—The only training center in the world set up especially to train spastics for work in industry was officially opened at Welwyn, Hertfordshire, about 18 months ago. Since its opening it has fitted 20 young men and women, at one stage thought to be untrainable, for industrial jobs. In the workshop carpentry, light engineering, printing, and other technical subjects are taught. The center has accommodations for 32 spastics between the ages of 16 and 25, and there is a long waiting list. When students arrive, many of them cannot read or write, and all have physical disabilities which make the simplest process a heavy task. As well as being taught the skills for "outside" jobs, they have to be taught how to live. Many have got into the habit of lying in bed for most of the day. Frequently there is nothing else for them to do, and they are in the way of other members of their families if they get up. The strict schedule of the center (set times for meals, work, and learning) gives them their first idea of normal working life. In many cases they are given their first hope of being able to take part in that life. Finding jobs for the trained students is the biggest problem and slows down the work of the center. Employers are sympathetic but wary and fellow workers are apprehensive at first. The man in the street is too often ignorant even of what spastic means. There have been a few total failures, but after 18 months this center has established itself as a realistic training ground doing a sound and valuable job.

Alcohol and Driving.—Drew and co-workers examined the effect of small doses of alcohol on driving skill (*Brit. M. J.* 2:993, 1958). The apparatus used was a "Miles motor driving trainer," in which the subject sits in a dummy car facing a translucent screen in a darkened room. Behind the screen is a perspex disk with a road scene painted on it and this is projected, very much magnified, on the screen by a lamp. As the driver operates the accelerator and steering wheel the car appears to progress along the road. The apparatus used gives the illusion of driving along a mile of road. The aspects of performance scored were accuray of tracking, speed of driving, and the control movements of steering wheel, accelerator, brake, clutch, and gear lever. Records were also made of the number of collisions with the side of the road that would be likely to happen under normal driving conditions. The subjects tested, 40 volunteers from the staff of the Road Research Laboratory ranging in age from 23 to 40 years, were given a 20% solution of alcohol flavored to disguise the alcohol content. The dose ranged from 0.2 to 0.65 Gm. of alcohol per kilogram of body weight. The alcohol level was determined in the blood, urine, and breath at intervals over a period of two and one-half hours. The peak blood alcohol concentrations from the doses given were about 20, 40, 60, and 80 mg. per 100 ml. and the ratio of urine alcohol to blood alcohol was 1.25 to 1. The best results with breath testing apparatus were obtained with one known as the "breathalyser," which gave values corresponding closely to the blood alcohol values. The other forms of apparatus either showed high constant errors or were difficult to use.

Performance began to deteriorate with blood alcohol concentrations of the order of 20 to 30 mg. of alcohol per 100 ml., corresponding to an intake of 0.2 to 0.3 Gm. per kilogram of body weight. The deterioration was progressive and linearly related to blood alcohol level. There was no evidence of a threshold effect. The impairment in performance was shown most clearly in the operation of the controls, particularly in the timing of steering wheel movements. Mean error showed an increase with an increase in blood alcohol, amounting to about 16% deterioration with a blood alcohol concentration of 80 mg. per 100 ml. Part of the increase in error was due to a significant tendency for subjects to move toward the right of the road after taking alcohol. Mean speed showed no significant change after alcohol, although there were marked individual differences in speed. Age, sex, and previous driving experience and drinking habits showed no relation to individual differences in response to alcohol, but personality ratings, especially those relating to extroversion and introversion, were definitely associated with driving performance.

Extroverts did not change either speed or control movements much, though they were less consistent in control movements, but showed large increases in error. Introverts changed speed markedly, but it was not possible to differentiate between those who slowed down and those who speeded up. Control movements were also increased in introverts. Error increased in some and not in others, but the mean error score was significantly less than in the case of extroverts, who on the whole did not seem to be bothered by the extra stress imposed by alcohol. They drove at much the same speed as normally and made few additional corrective movements, but made much greater errors than introverts. They were less consistent in their behavior than the latter and deteriorated more rapidly. Introverts on the other hand appeared to strive to compensate for the effect of alcohol and to be anxious to demonstrate their efficiency. If anything they overreacted to the situation, made more corrective movements, and changed their speed markedly, some even slowing down in an attempt to achieve greater accuracy, although they did not necessarily do so.

BUSINESS PRACTICE

This is the tenth in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

AS YOUR PRACTICE GROWS

As soon as it is financially possible, many physicians employ an office girl who can assume many of the routine duties of running the office, freeing the doctor to spend more time with his patients. She often serves as a combination office nurse, receptionist, secretary, and bookkeeper. She is particularly valuable in serving as the doctor's ambassador to his patients.

A few years ago an office aide was the exception rather than the rule—today four out of five practicing physicians employ at least one woman. This trend continues to increase as more doctors realize that managing a medical office means not handling all detail themselves but directing others to do much of it. Recent surveys point up the fact that physicians with office assistants can see more patients each day than doctors who go it alone.

As his practice grows, a physician may augment his office staff to include a registered nurse, in addition to a receptionist-secretary, a laboratory technician, or, perhaps, an x-ray technician.

Hiring an Aide

The first thing for a physician to consider when he reaches the point at which he is able to hire additional office help is "What duties do I want her to perform?" Depending on the kind of practice he has, some physicians may be primarily interested in a receptionist-secretary; others may prefer to employ a registered nurse who will spend a greater share of her time assisting with the medical side of the practice. Where a professional management consultant is available, it may be economical, in the long run, to seek such assistance in training office aides.

As a guide to physicians in hiring an assistant, Dr. Harold Mickelson, of Northeast Missouri State Teachers College, has worked up a list of more than 40 specific duties which an assistant might perform. His list is based on the results of a survey he conducted in cooperation with the American Medical Association to determine the ideal qualities, training, and skills of a medical secretary.

Here are just a few of the duties a girl often performs: (1) receives patients and office visitors; (2) answers the telephone; (3) makes appointments; (4) transcribes patients' medical records, histories, and similar data; (5) opens and sorts mail; (6) takes the doctor's letters; (7) prepares and mails financial statements to patients; (8) prepares insurance papers for doctor's signature; (9) pays office bills, makes bank deposits; (10) maintains daily and monthly financial records; (11) orders business and medical supplies; (12) handles office filing; and (13) operates equipment, such as mimeographs, in connection with the business side of the office.

On the medical side of the office she may (1) prepare patients for examinations; (2) weigh and measure patients; (3) take blood pressure, temperature, pulse rate; (4) assist the physician with minor medical procedures and surgery; (5) do routine laboratory tests and procedures; and (6) perform office "housekeeping duties," such as sterilizing instruments.

Depending on her particular type of medical training, she may operate such equipment as x-ray and electrocardiograph machines, give injections, or administer therapy of various types. However, the physician should always remember that he is responsible for the actions of any of his employees; all of her duties should be performed under his immediate supervision.

When the physician has prepared his own list of the duties he wishes his office aide to perform, his next step is to decide what kind of a woman he is seeking. He may want a young woman or he may prefer a more mature woman; he may have some personal preferences about educational background, special training, and personality qualities. The personality of the medical aide is of extreme importance. Because she is the doctor's key public relations person, she should be sincerely interested in people, friendly, and cheerful, as well as sympathetic and courteous. Her efficiency may be important, but it may be offset if she has the wrong kind of personality for the medical office.

How can a girl's personality qualities be determined? The doctor himself can rate her on appearance, voice, poise, intelligence, self-confidence, and similar personality qualities in his interviews with her. There are also interview guides and forms which a doctor can adapt to his own needs available from such companies as the Personnel Institute, 37 W. 47th St., New York, or the Psychological Corporation, 522 5th Ave., New York, if he wishes to use the job evaluation techniques of personnel experts.

There are many other qualities a doctor seeks in an ideal assistant. He looks for maturity, a quality not always determined merely by the age of the applicant. He searches for dependability, self-reliance, and composure, for he knows that there will be many times when he is out of the office and quick decisions about the way to handle a given situation must be made by the girl. She will need a sense of humor and patience to carry her through the difficult schedule of days, and she must be neat and accurate in all her duties. The ideal girl balances efficiency with personality.

Locating an Assistant.—When the doctor has carefully analyzed his own office needs, translated these into a detailed list of the duties he wishes an assistant to perform, and set down the personality qualities for which he is searching, he is ready to begin interviewing applicants. Where does he go to find job candidates who will qualify? Here are some suggestions: 1. Check with the local medical society and with colleagues who may know of girls seeking employment. 2. Check with local medical secretarial and medical assistant schools in the area. 3. Get the assistance of employment agencies. 4. Advertise in local newspapers or professional journals. 5. If there is a local medical assistants organization, contact its placement chairman. (A nationwide organization of doctors' aides, the American Association of Medical Assistants, now has state and local chapters in many states.)

In screening applicants, the physician should have each girl fill out a personal history form and should talk with her himself about her qualifications and the nature of the job. He will want to hold final interviews with the best applicants, and, when he narrows the selection down to one or two girls, he will wisely check with past employers for references.

Salaries.—Every young doctor is faced with deciding what to pay an aide. Few men establishing new practices are financially able to pay huge salaries. However, it is false economy to hire an unqualified girl merely because she will work for a small salary. Mistakes can be costly in a medical office and a poorly qualified office aide may even drive away patients.

The range of salaries for medical assistants varies around the country, just as do the range of physicians' incomes. A good general rule to follow is to pay on the same basis as a good secretary in business. Such information is easily obtainable from local employment agencies or from business friends who employ secretaries.

Though the doctor should have some salary schedule worked out before interviewing job applicants, he may find it necessary to alter it somewhat, depending on the experience, training, and personality of the girl he hires.

Some doctors prefer to employ a girl who has worked as a nurse in a local hospital or who has been employed by another doctor or just completed a training course in medical secretary–assistant work. Others prefer to take a young girl with relatively little training and teach her the job.

In addition to establishing equitable starting salaries, the doctor must also know when and how much to raise his employees' salaries from time to time in order to keep wages in line with those paid in the area and to provide continued job incentive. Too frequently raises are postponed until an assistant actually asks for a raise or becomes so dissatisfied she threatens to quit or actually does so. A raise in salary is an expression of appreciation for a job well done. With a comparatively small staff, some doctors find that individual salary raises from time to time are more effective than a blanket raise for all who work in the office. Some claim a raise is best given after an effective piece of work has been completed or just as the employee is leaving on her vacation. This garden-variety psychology is based on the premise that when an assistant leaves with an increased feeling of good will toward the office she will be anxious to return.

Other Job Incentives.—Most physicians offer sickness benefits, definite vacations, free medical care, and similar attractive benefits to their employees.

Some provide bonuses; others work out a percentage of collections arrangement for the girl who must follow up on collections, although this can lead to overaggressiveness on her part where patients are concerned. The physician is competing with industry and the business world for competent help, and consequently he, too, will find that fringe benefits are a real inducement in attracting well-qualified applicants.

Training an Aide

Too many doctors hire an office aide, then heave a great sigh of relief and say, "Now go to work." To do her job well she must be thoroughly trained in the specific office routine with her duties outlined clearly and specifically. A clear delineation of responsibilities must be made; this is especially important if a physician has more than one aide in the office.

Training an aide requires a liberal amount of understanding and patience. Some physicians even cut down on their case load to devote extra hours to the important training period, realizing that thoroughness at the beginning pays off later. The training period should emphasize showing, rather than merely telling the girl what to do. This entails explaining why certain things are done in the way they are done, rather than teaching by rote. A typed list of all her general duties and the schedule by which they are to be performed should also be provided the new girl.

Some doctors employ a girl for a trial period of a few weeks, so that both can see how the arrangement is working out. The moment a physician employs help, he becomes responsible for her social security deductions and payments, withholding tax deduction, workmen's compensation protection, and other insurances that may be required in his state. Information on these matters and the appropriate sources for the necessary forms is usually available from the county medical society.

If she handles patients' payments and bookkeeping duties, it is desirable to secure a bond for her, and it should be carefully explained that this is a protection for her as well as for the doctor.

During the training period, praise means a great deal to a girl who is trying to gain confidence on the job. She must be impressed with the importance of attention to detail and the absolute necessity for maintaining patients' office confidences. The doctor should correct her when she makes mistakes, but should not do so before patients. However, he should not expect her to learn everything the first day.

If the girl works out satisfactorily, she soon will become an important member of the office team and the doctor will wonder how he ever managed without his loyal, dependable office girl.

It is to his advantage to allow her occasionally to enroll in refresher courses sponsored by medical societies and medical assistants groups. He may even volunteer to pay her tuition for such postgraduate education, since in the long run it insures a better-run office and enhances the girl's pride in her work.

MEDICAL FILM REVIEWS

Life in a Cell: 16 mm., color, sound, showing time 13 minutes. Produced in 1956 by and procurable on purchase ($145) from World Wide Pictures, 4626 Van Nuys Blvd., Sherman Oaks, Calif.

The purpose of this film is to facilitate the teaching of the biological concepts of the basic life functions of a single-celled animal, the ameba. The film consists of a study, primarily by means of photomicrography, of a group of animals whose bodies are made up of just one cell, to learn how the basic life functions are performed in them. The biological concepts are considered in the form of questions: What does it mean to be alive? How can a single cell perform the basic life functions? How are the one-celled animals classified? Why are scientists interested in life in a single cell? Evidence is then presented that will direct the student toward scientific conclusions. This is an excellent film which would be very useful to create interest for discussion purposes. It is recommended for showing as a supplement to biology classes at the college and high school level. It could also be used at the junior high school level; however, for these classes considerable teacher supplement and vocabulary training would be required.

Cheiloplasty: Correction of Harelip: 16 mm., color, sound, showing time 24 minutes. Prepared by James W. Kelley, M.D., Tulsa. Produced in 1956 by Bud Woods Productions, Tulsa, for and procurable on loan from James W. Kelley, M.D., 204 Utica Square, Tulsa, Okla.

In this film, the method of operation for correction of harelip is demonstrated in detail and then the case of a 2-month-old child is presented. Each step of the procedure is shown, as well as the postoperative results. After this there is another demonstration of an operation done on an adult under local anesthesia. Here again, the steps of the procedure and the final results are shown. Included in the film are preoperative and postoperative photographs of several adults and children on whom cheiloplasty was performed. The techniques used are all acceptable and the photography is clear and allows the procedures to be seen easily. The sound and explanation are very good. The film can be recommended for general practitioners, pediatricians, and medical students.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Infarcts of the Pancreas. J. W. McKay, A. H. Baggenstoss and E. E. Wollaeger. Gastroenterology 35:256-264 (Sept.) 1958 [Baltimore].

This report is concerned with pancreatic infarction in the absence of acute necrotizing pancreatitis. The cases comprising this study were found among the records of 21,481 consecutive autopsies performed by the section of pathological anatomy at the Mayo Clinic during the years from 1924 through 1955. A thorough study of the autopsy protocols, anatomic specimens, photographs, and histological sections was made in all cases of pancreatic infarcts. An infarct was defined as tissue which had become necrotic because of impairment of its blood supply. The necrosis usually was of the coagulation type surrounded by a "zone of reaction" consisting of hemorrhage, dilated capillaries, and leukocytic infiltration. All the infarcts included were the size of one lobule or larger. The term "focal parenchymal necrosis" was used to designate necrotic acini in clusters smaller than one lobule. The term "focal fibrosis" was used to describe localized, fairly well-delineated areas of fibrous tissue, as opposed to diffuse interlobular fibrosis. The term "massive infarct" was used to describe instances in which one-fourth or more of the pancreas was involved. The term "malignant hypertension" was applied to cases in which the patient, during life, had had severe sustained essential arterial hypertension associated with edema of the optic disks.

Since isolated regions of acute hemorrhagic necrotizing pancreatitis could be confused with infarction, all instances of fat necrosis in extrapancreatic tissue or excessive peripancreatic or intrapancreatic hemorrhage were eliminated. Any evidence of diffuse inflammation of the pancreas in regions not immediately adjacent to infarcts was considered to be evidence of pancreatitis, and such cases were not included. Microscopic areas of fat necrosis, however, either isolated or adjacent to infarcts, were not eliminated, since they likewise could be ischemic in nature. Forty-one cases were found that fulfilled the required criteria; this represented an incidence of 0.19%. It was found that infarcts of the pancreas are most commonly associated with diseases characterized by occlusive lesions of the arteries, such as periarteritis nodosa and malignant hypertension. The relationship between infarcts of the pancreas and acute necrotizing hemorrhagic pancreatitis is not entirely clear, but this study indicates that lesions of each type may exist independently of the others and can be distinguished by their gross and histological appearance. It seems probable that, in some instances, pancreatic infarcts may produce significant clinical symptoms.

Among the 41 cases of pancreatic infarction, occlusive lesions of the arteries were found in 30 with thrombi or lesions of the arterial wall or both and in 3 with emboli. In the 8 cases with no demonstrable arterial occlusion, there was terminally either shock or congestive heart failure or both, which may have contributed to the production of ischemic infarction of the pancreas. The finding of frequent association of pancreatic infarcts with malignant hypertension and the failure to find any instance of acute necrotizing pancreatitis in 100 patients with malignant hypertension, studied by Hranilovich and Baggenstoss, seem to indicate that acute necrotizing pancreatitis is rarely caused by pancreatic infarction.

Observations on Staphylococcus Albus Septicemia in Mice and Men. I. M. Smith, P. D. Beals, K. R. Kingsbury and H. F. Hasenclever. A. M. A. Arch. Int. Med. 102:375-388 (Sept.) 1958 [Chicago].

Evidence obtained from cultures of blood of 9 patients affected with septicemia caused by Staphylococcus albus shows that this disease cannot always be dismissed as being due to contamination. A second culture should be taken, since overlooking a bacteremia due to this organism may have serious consequences for the patient. When the diagnosis of septicemia due to Staph. albus is made, it is necessary to determine the in vitro sensitivities of the isolated strain, as these sensitivities differ from strain to strain. The prognosis for the untreated patient is poor; therefore, prompt, carefully chosen, and prolonged antibiotic therapy is recommended. Death may occur late in the course of the disease, often unexpectedly, even though the blood stream has apparently been sterilized by treatment. Before the sensitivities are known, treat-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

ment with novobiocin and chloramphenicol can be recommended, but it should not be started until in vitro sensitivity tests have been made to a wide range of antibiotics.

Predisposing factors were common in the patients with this disease, such as rheumatic fever, previous illnesses requiring operation, and other manifestations tending to impair the general condition. The sexes were affected in a ratio of 2 males to 1 female, which was similar to that for patients with septicemia caused by Staph. aureus. The symptomatology included dyspnea, cough, and sore throat. Some patients complained of a pleuritic type of pain; shoulder, knee, and ankle joints were most often painful; chills and rash were common. Involvement of the cardiovascular system was frequently found at autopsy. Experiments in mice with 3 strains of Staph. albus obtained from the blood of patients rarely led to the death of the animals and seldom produced obvious evidence of the disease. Further studies to solve the problem of this disease are recommended.

Haemorrhagic Capillary Disorder Associated with Antihaemophilic Globulin Deficiency. L. S. Valberg and G. M. Brown. Medicine 37:181-196 (Sept.) 1958 [Baltimore].

An investigation was made on a large family group, many members of which suffered from one of the commoner inherited hemorrhagic disorders of capillaries. The great-great-grandfather of the family was an Italian fisherman who bore the name of Alfredo Purpura. He and all but one of his children migrated to America. In all, 278 members have been traced, and these comprise the entire family, save for possible descendants of the daughter who remained in Italy. Some of the 4th generation still bear the name Purpura, and some of these are affected by the disease. Laboratory investigation was carried out on 35 members of the family in 3 generations. Inquiry into a possible hemorrhagic disorder was made in 60 other cases. The information obtained on the others varied in completeness and accuracy. A history of abnormal bleeding was given by 15 persons, 5 males and 10 females. In one other case abnormalities were found in the laboratory which were similar to those found in the cases with a positive history of abnormal bleeding. The bleeding in affected members of the family was generally mild, though one 9-year-old boy died because of prolonged epistaxis. The most common cause of trouble was tooth extraction, and 12 of 16 persons had had significant bleeding after this type of trauma. Bleeding from minor cuts had been a problem in 7 persons and epistaxis in 5. Tonsillectomy had been accomplished without difficulty in 2 persons but had been followed by hemorrhage in 4. There were 4 cases of excessive bleeding after major surgery (discotomy, appendectomy and cholecystectomy, hysterectomy and appendectomy, and hysterectomy), but in 4 cases major surgery (thyroidectomy, renal lithotomy, exploration of elbow joint, and appendectomy) was carried out without reported complicating hemorrhage.

Summarizing the studies on this family and of a review of the literature, the authors say that the disease occurs in both sexes and is transmitted as a simple dominant independent of sex. For the most part the clinical features are mild. Typical findings include a variable prolongation of the bleeding time and a blood clotting abnormality characterized by variable clotting and prothrombin consumption times and a consistent abnormality in the thromboplastin generation test confined to the barium-sulfate-treated plasma. Evidence that the coagulation defect in this condition is antihemophilic globulin deficiency is supported by assay procedures for antihemophilic globulin and by evidence that antihemophilic globulin and the factor in normal plasma which corrects the defect in a patient's plasma behave similarly on storage, heating, freezing, cooling, ammonium sulfate saturation precipitation, dialyzation, barium sulfate or aluminum hydroxide adsorption, and Seitz filtration. The administration of fresh blood and prednisone in one patient improved the coagulation and vascular defects sufficiently to permit discotomy and spinal fusion.

Consideration of the patients studied and the report in the literature of cases of primary hemorrhagic disorder characterized by a normal platelet count and by a prolonged bleeding time or by abnormal capillary fragility (or sometimes by both) leads to the distinction of 3 major syndromes: (1) a pure capillary disorder; (2) a capillary defect associated with an abnormality in the humoral factors of the coagulation mechanism; and (3) conditions in which there is a capillary defect and an abnormality in platelet form and/or function.

A Study of Heart Disease in One Hundred Eight Hospitalized Patients Dying With Portal Cirrhosis. J. H. Lunseth, E. G. Olmstead and F. Abboud. A. M. A. Arch. Int. Med. 102:405-413 (Sept.) 1958 [Chicago].

The incidence and type of heart disease were evaluated in 108 consecutive patients who had moderate to severe portal cirrhosis at the time of death. The ages of these patients ranged from 26 to 83 years, with a mean age of 57.4 years and a standard deviation of 13.7 years. Twenty-six were women, and 82 were men. The examination revealed that 52 patients (48%) presented portal cirrhosis associated with severe heart disease, which was arteriosclerotic in 26, hypertensive in 9, valvular in 5, and hypertrophic in 12. The latter 12 patients constituted a frequency of 32.4% of cardiac hypertrophy among the 37 cirrhotics of this series who were found to have no clinical or pathological evidence of hypertension or valvular or arteriosclerotic heart disease. These patients presented a clinical picture of both heart and liver disease. Shortness of breath, edema of the legs, ascites, and chronic cough occurring in both conditions made the precise assignment of symptoms to either the heart or the liver difficult. Paroxysmal nocturnal dyspnea and orthopnea, more typical cardiac symptoms, called attention to the heart disease in 2 of these patients. The outstanding clinical characteristic of this type of heart disease appears to be the occurrence of cardiac enlargement in the presence of portal cirrhosis and in the absence of known causes for cardiac enlargement, such as hypertension, valvular heart disease, or arteriosclerosis. Seven of these patients had cardiac enlargement demonstrated either on physical examination or by chest roentgenogram. Tachycardia in the absence of fever or significant anemia should lead one to suspect cardiac involvement associated with portal cirrhosis. Apical systolic murmurs were heard in 5 of these patients without gross or microscopic evidence of valvular heart disease, and in at least 2 of these the murmurs were associated with significant anemia. Electrocardiograms gave evidence of premature auricular and ventricular contractions and intraventricular conduction defects of varying degree.

One of the most salient findings in this study was the fact that the idiopathic cardiac hypertrophy was significantly more frequent in patients with early and moderately advanced cirrhosis than in those with far-advanced cirrhosis. Cardiac hypertrophy in these patients was believed to be due to the increased cardiac output associated with peripheral vasodilation in the early stages of portal cirrhosis. These findings suggest that patients with portal cirrhosis not only have the common types of heart disease but also are apt to develop an idiopathic heart disease associated with portal cirrhosis itself.

Urinary Delta-Aminolevulic Acid and Porphobilinogen in Different Types of Porphyria. B. Haeger. Lancet 2:606-608 (Sept. 20) 1958 [London].

The author discusses whether the presence of some porphyrin precursor earlier than porphobilinogen in the urine might not be a more reliable criterion of the porphyria-carrier trait than the presence of porphobilinogen. Recently Mauzerall and Granick found that the precursor of porphobilinogen, delta-aminolevulic acid, was also present in large amounts in the urine of 2 patients with acute porphyria. They accordingly devised a method for quantitative determination of this substance. This method was used in making quantitative determinations of delta-aminolevulic acid and of porphobilinogen in urine from 50 healthy adults, from 50 healthy children (aged from 7 months to 14 years), from 34 patients with acute intermittent porphyria, and from 128 of their closest relatives, as well as from 12 patients with porphyria cutanea tarda.

All patients with latent or manifest acute intermittent porphyria showed a pathologically increased excretion of porphobilinogen in the urine. This, therefore, appears to be an obligatory diagnostic sign. In two-thirds of the patients the excretion of delta-aminolevulic acid was also increased. In all apparently healthy but genetically certain carriers of the disease, the urinary excretion of porphobilinogen, and usually of delta-aminolevulic acid as well, was increased. This suggests that the disease can be transmitted only by persons with latent or manifest porphyria. A third of the apparently healthy children (below 15 years of age) of patients with latent or manifest acute intermittent porphyria had biochemical disorders suggestive of porphyria. It is noteworthy that so many of these children had latent porphyria, since manifest porphyria is very rare in this age-group. In patients with porphyria cutanea tarda the urinary excretion of delta-aminolevulic acid and of porphobilinogen followed no regular pattern. Determination of the porphyrin content of the urine and feces thus appears more useful in the biochemical diagnosis of this type of porphyria.

Peripheral Vascular Complications in Diabetes Mellitus: A Survey of 3,600 Cases. D. W. Kramer and P. K. Perilstein. Diabetes 7:384-387 (Sept.-Oct.) 1958 [New York].

The authors studied the problem of the relationship of diabetes mellitus and the incidence of peripheral vascular complications in 3,600 patients with diabetes mellitus seen in private practice and in hospitals in Philadelphia between 1921 and 1956. The ages of the patients ranged from 10 to more than 80 years, and their cases varied from potential to severe type. A progressive rise in the incidence of peripheral vascular complications from 8.8% between 1921 and 1930 to 47.3% between 1952 and 1956 was observed. This finding prompted the authors' attempt to obtain more information about the factors involved in the relationship of diabetes to peripheral vascular disease by examining the cases of 1,600 patients, observed between 1942 and 1956, according to duration of the diabetes, severity of the disease, age, and sex. Results showed that duration of diabetes alone is not a significant factor. The highest incidence of complications of the peripheral arterial system was in patients with diabetes of 1 to 5 years' duration. The next highest occurred in patients with diabetes of 6 to 10 years' duration. Similarly, the severity of the diabetes is not a definite factor, because the vast majority of complications have occurred in patients with milder forms of the disease. Age and sex do not offer any significant explanation for the rise of the incidence of vascular complications. The findings of the survey suggest that the basic cause for atherosclerosis might best be sought in other fields. Further investigations in the field of metabolic disorders, besides cholesterol and carbohydrates, may give added information.

Sarcoidosis of the Spinal Cord: Report of a Case with Remission Associated with Cortisone Therapy. A. Moldover. A. M. A. Arch. Int. Med. **102**:414-417 (Sept.) 1958 [Chicago].

While sarcoidosis is a relatively common disease, involvement of the spinal cord, which occurred in a 24-year-old man with sarcoidosis, is so rare that the case appears to be of interest. The patient noticed pain in his calves 5 months before he was first seen in consultation, followed by pain in his right hip and lower back. For the past two months he had had difficulty in walking a straight line; he could not stand on his toes, climb stairs, walk rapidly, or stand on one leg. One week previously impotency and difficulty in urination developed, and he consulted an urologist. The prostate was normal, but his urinary condition was diagnosed as a cord bladder. The patient complained of extreme general exhaustion and weakness.

Physical examination revealed a tall cachectic young man, walking with a shuffling gait, unable to lift his feet from the floor. A generalized lymphadenopathy, including cervical, axillary, and inguinal nodes, was found. There was no tenderness of the spinal column. Chest roentgenograms showed enlarged hilar lymph nodes and diffuse pinpoint opacities throughout both lung fields. The gastrointestinal series showed an enlarged spleen indenting the greater curvature of the stomach. Neurological examination revealed bilateral hyperalgesia, impaired sensitivity to pin prick and touch over the left saddle-seat area, normal abdominal but depressed cremasteric reflexes, and absent knee and ankle jerks. The Babinski response was normal. The protein content of the spinal fluid was 128 mg. per 100 cc., and the sugar content was 40 mg. per 100 cc. An inguinal lymph node was removed for biopsy, and histological examination was consistent with sarcoidosis. The patient was treated with corticotropin in daily intravenous injections of 25 mg. (1 mg.=1.14 U. S. P. units); the corticotropin was dissolved in 500 cc. of 5% dextrose in water and was given slowly during 8 hours for 8 consecutive days. A dramatic response was obtained on the third day of treatment when bladder function was restored to normal; the patient was able to walk normally, the exhaustion disappeared, and he was discharged from the hospital in a much improved condition. All the symptoms and signs returned 6 weeks later, though, and the patient was then given cortisone by the oral route: 300 mg. the 1st day, 200 mg. the next 2 days, and 150 mg. for the next 10 days. The daily dose of cortisone was then reduced to 100 mg. Two days later insomnia developed, and a dose of 75 mg. was given. Two grams of potassium chloride was also administered daily. As before, the reaction to steroid therapy was excellent and was manifested by marked increase in appetite after administration of the first dose of the drug.

The disease in this patient was characterized by the alternation of prompt remissions when steroid therapy was given and relapses whenever it was stopped; after 2½ years of treatment cortisone was withdrawn. One and a half years after termination of the therapy, the roentgenograms showed for the first time normalization of the lung, the neurological findings were negative, and the patient resumed normal sexual activity. The results obtained with steroid therapy in this patient with sarcoidosis indicate its value in this condition.

Familial Congenital Hyperplasia of the Adrenal Cortex. G. Birke, E. Diczfalusy, L.-O. Plantin and others. Acta endocrinol. **29**:55-69 (Sept.) 1958 (In English) [Copenhagen].

The authors report on a family consisting of the parents, aged 47 and 44 years, and of 6 children, 3 of whom, aged 15 years, 12 years, and 8 weeks, had congenital hyperplasia of the adrenal cortex manifested as female pseudohermaphroditism; the other 3 children, 2 girls, aged 13 and 10 years, and 1 boy, aged 8 years, were normal both in weight and height and concerning their sex organs. Analysis of the steroid secretion in the urine was done in all 8 members of this family. The father, mother, and 3 healthy children showed a normal excretion pattern of 17-ketosteroids, 17-hydroxycorticosteroids, androgens, and estrogens. The youngest of the 3 female pseudohermaphrodites died before any steroid analyses could be carried out. The other 2 children with adrenocortical hyperplasia showed a substantially increased excretion of both 17-ketosteroids and 17-hydroxycorticosteroids as well as pathological changes of their excretion patterns. Androsterone showed a greatly increased output, but etiocholanolone could not be identified with certainty. The increased excretions of 11-oxy-17-ketosteroids consisted mainly of those of 11-keto-etiocholanolone and 11 beta-hydroxyandrosterone which were isolated and identified by infrared spectroscopy; 11 beta-hydroxyetiocholanolone could not be detected. An indirect analysis of the 17-hydroxycorticosteroid pattern revealed the presence of large amounts of pregnanetriol. Measurable amounts of pregnan-3 alpha,17 alpha,21-triol-20-one (tetrahydro-S) were also observed in the urine. In neither of these 2 children was the excretion of the latter accompanied by hypertension. Tetrahydrocortisone and 11-keto-pregnan-3,17,20-triol were also identified, but no 11 beta-hydroxylated corticosteroids could be detected. The estrogen pattern was characterized in both patients by the complete absence of estriol. The older patient, who grew up as a girl, showed pronounced masculinization at the age of 14 and underwent bilateral subtotal adrenalectomy; after this operation substantial amounts of estriol were detected in the urine.

The assays in these 2 patients with adrenocortical hyperplasia thus revealed a partially new steroid excretion pattern characterized by the presence of tetrahydro-S despite the absence of hypertension, a defect in the 11 beta-hydroxylating mechanism, a dichotomy between androsterone and etiocholanolone excretion, and a disturbed estrogen pattern. These findings and those reported by other workers suggest very strongly that in congenital adrenocortical hyperplasia a number of different defects may arise in the enzymatic systems of the adrenal glands, more or less marked in different cases. Although a defect in the formation of hydrocortisone from its precursors appears to be a common factor in most of the patients with adrenocortical hyperplasia, various additional enzymatic defects, giving rise to different types of steroid patterns, also appear to be present.

Marfan's Syndrome. F. Erichsen and P. Svane-Knudsen. Ugesk. laeger 120:1121-1126 (Aug. 21) 1958 (In Danish) [Copenhagen].

Arachnodactyly or congenital mesodermal dystrophy (Marfan's syndrome) designates a constitutional anomaly of hereditary character. In patients without cardiovascular complications or grave kyphoscoliosis, the prognosis for life is considered good. Since there is ectopia lentis in 50 to 75% of the cases, the state of vision often becomes decisive for the prognosis as to ability to work. Report is given on 9 patients with Marfan's syndrome whose typical cases have not previously been described. These patients represented 3 families, and information was also available on 10 relatives with the anomaly. Of the 2 patients with kyphoscoliosis, one died 2 weeks after the examination, probably of cor pulmonale. No cardiovascular lesions were demonstrated in the 8 surviving patients. Marfan's syndrome should be borne in mind, especially in mass examinations of school children or in the practice. Children with the anomaly can be helped by regular consultations with orthopedist and ophthalmologist and by advice as to choice of career. Many persons with the disorder are fully able to work, even at physically demanding occupations.

SURGERY

Leiomyosarcoma of the Stomach. L. W. Mason and V. R. Jablokow. J. Internat. Coll. Surgeons 30:285-293 (Sept.) 1958 [Chicago].

The incidence of leiomyosarcoma of the stomach is about the same in both sexes, and the age of onset is usually one decade earlier than that of carcinoma. The prognosis after surgical removal (leiomyosarcoma is not a radiosensitive tumor) is relatively good. In this discussion 3 patients are alive and well 4, 7, and 8 years, respectively, after operation. Early diagnosis is extremely important and can be made by gastrointestinal hemorrhage, epigastric distress resembling peptic ulcer, a palpable epigastric mass, roentgenologic evidence, gastroscopic examination, and laparotomy. Distress is usually relieved by taking food and frequently by taking alkali in spite of achlorhydria (present in about 25% of cases). These tumors may vary from 2.5 to 25 cm. in diameter, are lobulated or nodular and rubbery, and may be found anywhere in the stomach, although rarely in the pyloric and cardial areas. They are usually less fixed and less hard and nodular than carcinoma. Roentgenologic diagnosis can rarely be accurately accomplished. In these 3 cases it could only be stated that a filling defect was present. Hypochromic macrocytic anemia is usually present, often in direct proportion to the duration of the disease. Usually there is no relation to gastric acidity. Free hydrochloric acid is lacking in the patient with leiomyosarcoma of the stomach more frequently than in the normal person, but it is much less common than in patients with carcinoma. Appetite usually remains good, and loss of weight occurs late or not at all. Many patients appear to be in good physical condition even in the terminal stages. The leiomyosarcoma is a slow-growing tumor, prone to metastasize late, although it infiltrates locally. It is usually encapsulated and spreads by displacement rather than by invasion.

Venous Shunts in the Surgical Management of Bleeding Esophageal Varices. R. W. Youngblood. J. Tennessee M. A. 51:357-364 (Sept.) 1958 [Nashville].

The author reports on 9 female and 15 male patients with portal hypertension associated with esophageal varices who underwent 25 venous shunting procedures (11 portacaval and 14 splenorenal shunts) at the Vanderbilt University Hospital in Nashville, Tenn., between May, 1951, and March, 1958. Twenty-one of the 24 patients had intrahepatic block, and only 3 had extrahepatic block. Of the 21 patients with intrahepatic block, 12 had Laennec's or alcoholic cirrhosis, 5 had posthepatic cirrhosis, 3 had biliary cirrhosis, and 1 had cirrhosis whose cause was unknown. Of the 3 patients with extrahepatic block, 2 were children with thrombosis of the portal vein secondary to omphalitis, and 1 was an adult with cavernomatous transformation of the portal vein. Preoperatively all patients except one had an average of 2 attacks of major hemorrhage. The surgical procedure usually consisted of end-to-side anastomosis with continuous, nonabsorbable suture material.

There were 2 operative deaths; one patient died 8 days and the other 15 days after the operation, both in hepatic coma. Three other patients died, one 8 weeks after the operation and two 4 years after the operation. Autopsies were performed on 4 of the 5 patients, and the shunt was patent in each of them. None died of hemorrhage. Only 2 other patients had subsequent bleeding during follow-up periods ranging up to 7 years; in one of these, bleeding followed thrombosis of a splenorenal shunt, the only instance of thrombosis in the entire series. The relatively low mortality rate and the rarity of complications and recurrent bleeding or thrombosis of the shunt are impressive when contrasted with older series of patients under nonsurgical management, who had mortality rates varying from 50 to 80%. Emphasis should be placed on the fact that bleeding is the most frequent cause of death in patients with esophageal varices. Therefore, venous shunting should no longer be considered as a palliative procedure, since other complications of cirrhosis may now be largely controlled with modern medical management. Portal-systemic shunts are feasible, with a low mortality rate even in poor-risk patients with cirrhosis. Liver function and ascites are infrequently improved by a shunting procedure alone but may be improved by medical means.

Transection of the Hypophyseal Stalk in the Management of Metastatic Mammary Carcinoma. G. S. Dugger, J. Van Wyke and J. F. Newsome. Am. Surgeon 24:603-608 (Sept.) 1958 [Baltimore].

Hypophysectomy has been known to be followed by improvement in 50% of patients with metastatic breast carcinoma; however, total hypophysectomy is difficult and is not always achieved. The authors review attempts to achieve functional hypophysectomy, and, on the basis of experimental evidence, the procedure they used to cause a functional hypophysectomy consisted of transection of the infundibular stem or hypophyseal stalk and the placement of a disk of impervious material across the sella turcica. Thus, the revascularization of the hypophysis by vessels from the hypothalamus, specifically the vessels of the hypophyseal portal system, became unlikely.

Beginning in July, 1955, this operation was performed on 15 patients with advanced metastatic carcinoma of the breast. Endocrine function was assayed preoperatively and in the patients who survived sufficiently long postoperatively. Studies were made of the uptake of radioiodine (I^{131}) and protein-bound iodine, of the excretion of gonadotropins, 17-ketosteroids, and 17-hydroxycorticosteroids, and of the response of plasma 17-hydroxycorticosteroids to the adrenocorticotropic hormone. Six of the 15 patients with metastatic mammary carcinoma showed a remission, 4 gained no benefit, 1 died as a result of the operation, and in 4 patients the operation was too recent to permit evaluation. Average duration of remission was 6.6 months. This was less than that reported for total hypophysectomy but will probably improve with better selection of cases. Whether the quality of the remission is the same as that after total hypophysectomy has not been determined.

The Surgical Treatment of Cushing's Syndrome. F. Glenn, R. C. Karl and M. Horwith. Ann. Surg. 148:365-374 (Sept.) 1958 [Philadelphia].

Thirty-two patients with adrenal cortical hyperfunction (Cushing's syndrome) have been evaluated during the past 24 years at the New York Hospital-Cornell Medical Center. All but 2 were women. The peak age of incidence was in the 4th decade. The most common physical complaint with muscular weakness or fatigue, which in 3 patients resulted in extreme disability. A 52-year-old woman had such severe muscular weakness that neurologists had entertained such diagnoses as muscular dystrophy and peripheral neuritis. Amenorrhea or menstrual irregularities developed in 24 of 28 women who were experiencing normal menstrual periods prior to the onset of their symptoms. A moon facies was noted in 25 patients, while truncal obesity with supraclavicular and cervicodorsal fat pads and thin tapered extremities occurred in 19. Facial and body hirsutism was frequently seen. Scalp hair tended to pull out easily. Atrophic skin, facial plethora, acne, and increased bruisability were common, but purple striae occurred in only 9 instances. Psychiatric problems varied from increased irritability to severe depression. Since an adequate method of determining serum and urinary 17-hydroxycorticoid levels has become available, this has been the most useful laboratory examination in the diagnosis of Cushing's syndrome. The 17-hydroxycorticoid values were elevated in 19 of the 22 patients in whom the test was employed, and the urinary 17-ketosteroid levels were increased in 15 of 28 patients. Other frequently encountered laboratory findings were diabetic glucose tolerance responses, eosinopenia, leukocytosis, increased insulin resistance, lymphopenia, alkalosis, and polycythemia. There were 14 instances of osteoporosis.

No satisfactory medical therapy is available for Cushing's syndrome, but excision of the hyperfunctioning adrenal cortical tissue has frequently induced permanent remission. Thirty of the 32 patients were operated on, the authors favoring a lateral incision with resection of the 12th rib. Transabdominal exposure of the adrenal glands is reserved for patients with severe osteoporosis who cannot be placed in the lateral position without risking a compression fracture of a vertebral body and damage to the spinal cord. One of the first patients had what appeared to be normal adrenals, and only biopsy specimens were taken. This was a 9-year-old boy who subsequently underwent a spontaneous remission. Twenty patients had a total adrenalectomy. Nine patients underwent unilateral adrenal resection for either adenoma or hyperplasia. There were no deaths among the patients treated surgically. The duration of cortisone therapy varied from 2 days to several weeks in patients in whom adenomas were resected.

Within weeks after adequate surgical therapy, there is a redistribution of body fat, so that a more normal appearance is soon evident. Muscular strength slowly improves, and normal menstrual periods return. Osteoporotic bones gradually recalcify. The blood pressure often returns to normal levels. Although facial hirsutism usually subsides completely, it persisted in some patients. A persistent low-grade fever, sometimes accompanied by mild diarrhea, was experienced by some of the totally adrenalectomized individuals. In 3 patients who had both adrenals excised, transitory hypercalcemia and hyperphosphatemia developed postoperatively and was accompanied by such symptoms as fever, anorexia, nausea, vomiting, muscular weakness, polydipsia, and polyuria. In one patient, in whom all but a small remnant of adrenal tissue was removed, there developed 3½ years later a complete ophthalmoplegia on the right and bitemporal hemianopsia. The spinal fluid was bloody, and skull x-rays revealed an enlarged sella turcica which had not been present previously. Diabetes insipidus then became evident. A craniotomy was performed, and the clinical impression of a hemorrhage into a basophilic adenoma was confirmed. When adequate medical facilities are available, totally adrenalectomized patients can be maintained safely.

Cortisone as Cover for Major Surgery in Advanced Pulmonary Tuberculosis. J. R. Edge. Lancet 2:604-605 (Sept. 20) 1958 [London].

The author reports on 17 patients (14 male and 3 female) with far-advanced pulmonary tuberculosis for whom major surgery was considered to offer the only real hope of permanently arresting the disease. Their ages ranged from 26 to 58 years. The operations carried out were pneumonectomy in 5 patients, lobectomy in 4, local excision of cavity in 1, and thoracoplasty in 7. The patients have been followed up for from 6 to 21 months after operation. When the resting 24-hour 17-ketosteroid excretion was found to be low, cortisone therapy by mouth was started 3 days before operation in a daily dose of 100 mg. (25 mg. every 6 hours); this dosage was continued for a week after operation and then reduced, in weekly steps of 25 mg., to 75, 50, and a final 25 mg. daily. The total duration of treatment was 4 weeks. There were 3 postoperative deaths from definitive complications unrelated to stress. The remaining 14 patients had no postoperative complications, apart from transient basal collapse in one instance. The postoperative course was remarkably free of incident; the patients remained free of fever, dyspnea, hypotension, and tachycardia and on the day after operation looked and felt none the worse for the operation. The pink color and lack of any suggestion of dehydration were particularly striking. Wound healing proceeded quite normally in all patients. It is suggested that the replacement of deficient endogenous adrenal secretion contributed substantially to the recovery of the patients.

Clinical Aspect and Therapy in Patients with Tuberculosis of the Cervical Lymph Nodes. E. Beck, H. Behrendt and J. Kastert. Tuberkulosearzt 12:573-580 (Sept.) 1958 (In German) [Stuttgart, Germany].

The authors report on the results of combined surgical and tuberculostatic treatment in 949 patients, ranging in age from 10 to 60 years, with tuberculosis of the lymph nodes who were admitted to the sanatorium "Sonnenwende" in Bad Dürkheim, Germany, between 1949 and 1957. Treatment consisted of skin incision in the direction of folds of the skin, removal of the surface abscesses of caseous necrosis, and wide dissection of all palpable and visible subjacent lymph nodes. Roentgenograms before or during the operation helped to locate the calcified lymphomas. Complete extirpation of all caseous lymph nodes is necessary in order to guarantee a complete cure. Preceding the closure of the wound, streptomycin (0.5-1.0 Gm.), isoniazid (0.25-0.5 Gm.), and penicillin (200,000-400,000 units) were applied to the wound. Tuberculostatic therapy with streptomycin and isoniazid was started 3 to 5 days before the operation and was continued for the whole period of hospitalization. After the operation amithiozone (Conteben) was substituted for streptomycin, but, if liver damage existed, aminosalicylic acid (PAS) was used; cycloserine was recently given a trial.

Of the 949 patients, 553 had received previous treatment, while 396 had had no treatment. In 50% of the pretreated patients no tuberculostatic therapy had been given, and in 70% tonsillectomy had been omitted. Two hundred forty-five patients had received irradiation treatment without any success, and in 97 fistulas had developed. In all patients who had received irradiation treatment, connective tissue changes occurred and rendered operation more difficult. All the patients who had received previous irradiation still had palpable lymph nodes which made surgical treatment necessary. Of 450 patients with involvement of one group of lymph nodes, 447 obtained complete cure, and 3 had recurrences. Of 222 patients with unilateral generalized lymph node involvement, 165 obtained complete cure, and 10 had recurrences. Of 112 patients with bilateral generalized lymph node involvement, 80 obtained complete cure, and 7 had recurrences. Of 41 patients with involvement of several groups of lymph nodes in nonadjacent areas of the body, 37 improved, and 4 had recurrences. The incidence of recurrence depended more on the extent of the tuberculous process, i. e., the number of groups of lymph nodes involved, than on the more or less advanced stage of the lesions; the incidence of recurrence definitely depends on the possibility or impossibility of complete surgical removal.

Early surgical intervention is recommended, not only to prevent disfiguring scars but also to shorten the toxic contamination of the entire organism by the tubercle bacilli. Irradiation therapy has lost its value in an era in which operative removal of tuberculous foci has become possible with the aid of tuberculostatic agents.

Tumors of the Carotid Body (Chemodectomas). E. Lima Basto. Arq. pat. 30:305-334 (July) 1958 (In Portuguese) [Palhava, Lisbon].

Tumors of the carotid body, so-called chemodectomas, are rare. As a rule, they appear in persons of either sex, between the ages of 20 and 50 years, are unilateral (on the left side of the neck), and are either unilobular or multilobular. Externally the tumor grows very slowly, but internally it causes massive involvement and compression of the carotid artery and its bifurcation, the nerves, regional lymph nodes, the muscles, larynx, and pharynx. These tumors are histologically benign, but they may become malignant and result in metastases. Radium and roentgen-ray treatments are ineffective. The best treatment is surgical.

Three men with tumor of the carotid body were observed at the Hospital of the Instituto Portugués de Oncologia, of Lisbon, during the period 1956-1957. They were between the ages of 19 and 35 years. One of the patients occasionally had convulsions on the left side of the face and in the left arm. The tumors had appeared 5 or 6 years before consultation. They were unilateral and about the size of an orange. The cervical and submandibular lymph nodes were enlarged in all cases. Biopsy of these nodes showed either chronic lymphadenitis or atypical forms of lymphogranuloma. There were no metastases in any of the patients.

Operation consisted of dissection of the tumor, with conservation of the carotid artery in one patient in whom it was found that the tumor was causing compression of the carotid artery without entering its wall. In the other 2 patients, the tumor had involved the carotid wall; the carotid artery was ligated and resected in order to make possible complete extirpation of the tumor. There were no postoperative deaths. After the operation 2 patients continued in good health. The patient who had occasional convulsions before the operation was hospitalized 6 weeks afterward with a syndrome of intracranial hypertension. A decompressive craniotomy failed. An autopsy showed multicentric diffuse gliomatosis. There were no cerebral metastases of the tumor of the carotid body. The author advises an early operation before the tumor involves the carotid.

Primary Chief-Cell Hyperplasia of the Parathyroid Glands: A new Entity in the Surgery of Hyperparathyroidism. O. Cope, W. M. Keynes, S. I. Roth and B. Castleman. Ann. Surg. 148:375-388 (Sept.) 1958 [Philadelphia].

Originally hyperparathyroidism and an adenoma of a parathyroid were regarded as synonymous, since, until 1933 no other type of anatomic disorder of the parathyroid glands was reported in patients with hyperparathyroidism. Beginning in 1934 and subsequently, other lesions of the parathyroids have been recognized. Since 1952, 10 patients with primary hyperparathyroidism have been encountered with a type of parathyroid hyperplasia distinct from adenoma, carcinoma, and the water-clear cell hyperplasia. All the parathyroid glands are enlarged by the disease process, the cells are predominantly of the nonvacuolated chief-cell type, and the entity is being called "primary chief-cell hyperplasia." It is essential that the entity be recognized at operation if secondary operations are to be avoided. The enlargements are most readily confused with adenoma, especially if only one gland is exposed. Five per cent of the first 200 patients with primary hyperparathyroidism cared for at the Massachusetts General Hospital in Boston have turned out to have this condition.

Four of the 10 patients with primary chief-cell hyperplasia also had tumors of the pancreas and pituitary gland, and it is suspected that this condition, previously described as "adenomatous hyperplasia" and "multiple adenoma," will prove to be the common type of parathyroid disease in patients with multiple endocrine abnormalities. Grossly, the cut surfaces of the individual glands present an ill-defined nodularity, which is more evident microscopically. The gross and microscopic appearance of a single gland may be insufficient to distinguish chief-cell hyperplasia from adenoma, and examination of all 4 parathyroid glands may be necessary to establish a definite diagnosis. The surgical treatment consists of total resection of 3 glands and a subtotal resection of the 4th.

Prescalene-Lymph-Node Biopsy. J. T. Wilson, E. G. Laforet, and J. W. Strieder. New England J. Med. 259:615-618 (Sept. 25) 1958 [Boston].

Prescalene lymph node biopsy was performed in a series of 153 patients with intrathoracic disease at Boston City Hospital. There were 148 cases in which lymphoid tissue was identified. Of these, 29 (20%) yielded histological evidence of the underlying pulmonary disease. Prescalene node biopsy was successful in 18% of the cases in which all other diagnostic methods short of exploratory thoracotomy had been unavailing. It is believed that, in view of the minimal risk, good diagnostic yield, and important prognostic significance, prescalene lymph node biopsy continues to be justified in the presence of intrathoracic disease. On appropriate indication the biopsy may also constitute a useful diagnostic adjunct in the patient who is hospitalized for pulmonary tuberculosis. In the present series of 20 patients undergoing this procedure, positive diagnostic information was obtained in 7. The yield of significant histological data was highest when the underlying pulmonary disease was sarcoidosis and lowest when it was tuberculosis. Bronchogenic carcinoma occupied an intermediate position.

The major indications for prescalene lymph node biopsy in patients hospitalized for pulmonary tuberculosis are as follows: inability to obtain bacteriological confirmation of the diagnosis of pulmonary tuberculosis, thus indicating that search for nontuberculous disease be intensified; x-ray findings suggestive of bronchogenic carcinoma; delay in x-ray improvement despite adequate medical therapy; and unexpectedly good clinical condition in the presence of roentgenologically extensive pulmonary disease. Bacteriological study of the cut surface of the resected lymph nodes is occasionally of value and should be performed more frequently. Although not done in this series, mycologic study of the resected lymph nodes is also recommended when the diagnosis is obscure.

Syndrome of Left Ventricular–Right Atrial Shunt: Successful Surgical Repair of Defect in Five Cases, with Observation of Bradycardia on Closure. F. Gerbode, H. Hultgren, D. Melrose and J. Osborn. Ann. Surg. 148:433-446 (Sept.) 1958 [Philadelphia].

A membranous ventricular septal defect which has its major flow into the right atrium has been recognized for many years. Recent advances in intracardiac surgery have made it possible to close such defects. This paper describes the essential clinical features of 5 instances of left ventricular–right atrial shunt. All were successfully closed with the aid of extracorporeal circulation. The first patient was a boy, who was first seen at the age of 10 years for the evaluation of a heart murmur. At operation at the age of 15, a small septal defect was found penetrating the septal leaflet of the tricuspid valve near its margin of insertion. The heart was stopped and the defect repaired under direct vision. After closure of the atrial incision, ventricular fibrillation appeared, but this was effectively reversed by cardiac massage and electrical defibrillation. Four months after surgery, the boy was asymptomatic even during strenuous activity.

In the second patient, a girl, the mother had discovered a heart murmur when the child was 18 months old. Operation at the age of 10 years revealed a defect in the upper margin of the septal leaflet at the tricuspid valve. This defect could be closed easily with the index finger, eliminating the thrill, slowing the heart, and raising the systemic blood pressure. It was decided that this lesion could best be corrected with the use of extracorporeal circulation. The operation was, therefore terminated and the patient allowed to recover. At the second operation, 8 months later, with the aid of extracorporeal circulation, the opening between the left ventricle and the right atrium was closed with interrupted sutures. There was also a defect in the upper margin of the septal leaflet of the tricuspid valve directly overlying the opening. The atrium was repaired and the heart restarted in normal sinus rhythm. There has been a remarkable improvement in physical capacity.

The third patient, a 5-year-old boy, had severe symptoms due to plumonary congestion, and there was doubt whether or not he would survive. Postoperatively he has shown remarkable improvement. The fourth patient was a 42-year-old man. He had severe cardiac symptoms; the physical signs were a ventricular septal defect. Catheterization data suggested an atrial septal defect. Postoperative recovery was uneventful, and there was no residual murmur. The fifth patient, a 17-year-old Eskimo girl, had a left ventricular–right atrial shunt which on catheterization was interpreted to be a ventricular septal defect.

The high ventricular septal defect associated with a defect of the septal leaflet of the tricuspid valve allows left ventricular blood to enter the right atrium. Of unusual interest was the finding that on manual closure of the defect there was a bradycardia and rise in systemic blood pressure. This phenomenon, previously described by Nicoladoni and Branham on closure of a peripheral arteriovenous fistula, has been thought to be due to the elimination of the reduced peripheral resistance at the fistula, which allows the full output of the left ventricle to pass into the systemic circulation. This causes stimulation of the carotid sinus mechanism and the depressor nerves, which then reflexly, through the vagus, slows the heart. It is believed that the effect shown here is similar physiologically to that observed on closure of an arteriovenous fistula, for the left ventricular–right atrial shunt is essentially an internal fistula. This phenomenon was observed in all 5 patients operated on.

Surgical Considerations of Occlusive Disease of the Abdominal Aorta and Iliac and Femoral Arteries: Analysis of 803 Cases. M. E. De Bakey, E. S. Crawford, D. A. Cooley and G. C. Morris Jr. Ann. Surg. 148:306-324 (Sept.) 1958 [Philadelphia].

This report is concerned with observations derived from an analysis of surgical experience during the past 5 years with 803 cases of occlusive disease of the aorta and iliac and femoral arteries. The obstructing lesion in chronic arteriosclerotic occlusive disease of the lower extremities was usually well localized and segmental in nature. There were 2 major groups of lesions, namely, aortoiliac occlusion and femoral occlusion. In the former group of 448 cases, 44% were characterized by complete aortic occlusion and 56% by incomplete occlusion. Associated occlusive disease of the peripheral arterial bed was present in 18% of these cases and was more frequently encountered in patients with incomplete aortic occlusion. Arteriographic studies were important in providing precise knowledge concerning location and extent of occlusive process to permit effective therapy.

Treatment of aortoiliac occlusive disease was directed toward restoration of normal circulation. Three types of surgical procedure were employed, namely, thromboendarterectomy, excision with graft replacement, and bypass graft. It was found that the indications for each of these procedures were dependent on location, extent, and nature of the occlusive process as well as on certain systemic factors; lumbar sympathectomy was a desirable supplemental procedure when there was associated peripheral disease, with secondary narrowing or occlusion in the smaller distal part of the arterial bed. The results of surgical treatment in aortoiliac occlusive disease were excellent. Circulation through the major arterial channels was restored in about 95% of the patients. Associated cardiac and renal disease constituted the major cause of operative mortality in 2.7%. Cardiac disease, mostly in the form of coronary thrombosis, was also the primary cause of death among the 9 patients whose late deaths occurred from 1 to 30 months after discharge from the hospital. The long-term results in these cases of aortoiliac occlusion have been satisfactory, as evidenced by the fact that recurrent occlusion was encountered in only 8 patients after varying periods ranging from 3 to 27 months. In all but one of these patients, who refused operation, the circulation was restored by a second operative procedure consisting of a bypass graft.

The pathological features of femoropopliteal occlusive disease vary, but certain patterns may be recognized. They may be classified into 3 groups: (1) those in which the occlusive lesion is discrete and well localized with relatively normal arterial elements above and below the occlusion; (2) those in which the process involves a considerable portion, if not most, of the superficial femoral artery but with patency of the popliteal artery and the distal part of the arterial bed; and (3) those with still more extensive and diffuse obliterative disease extending well down into the smaller vessels of the calf. Arteriographic studies are essential in the recognition and in the surgical treatment. Patients in the first 2 groups are amenable to treatment directed toward restoration of normal circulation, whereas those in the third are not and may be best treated by lumbar sympathectomy. Thromboendarterectomy may be satisfactorily employed in those in the first group, but in the second the bypass graft is the procedure of choice.

Of the 353 patients with occlusive disease of the femoral artery, 90% were treated by means of the bypass graft. Excision and graft replacement, which was employed in 19 cases in the early period of this experience, has been virtually abandoned in favor of the bypass graft. Endarterectomy is still considered a desirable procedure, but conditions in which it is indicated are rarely observed. Despite the greater difficulties imposed by this form of occlusive disease as compared with the more proximal form, the results of treatment have been gratifying, with restoration of normal pulsatile circulation in 84% of the patients. Long-term results were also satisfactory, as evidenced by the fact that recurrent occlusion was observed in only 14% of the patients over a period of 3 weeks to 38 months after discharge from the hospital. A second operation was performed on 27 of the 41 patients with late failure, and restoration of circulation was achieved in 20 patients.

Primary Splenic Pancytopenia: Dramatic Effect of Splenectomy. J. Tapie, J. Monnier, J. Poulhes and others. Presse méd. 66:1389-1392 (Sept. 13) 1958 (In French) [Paris].

The beneficial effect that may be exerted by splenectomy in patients with primary splenic pancytopenia was strikingly illustrated in the case of a 16-year-old girl whose life was endangered by repeated hemorrhages. The combination in this patient of febrile anemia, moderate enlargement of the spleen, and a hemorrhagic syndrome suggested the diagnoses of cryptoleukosis, aplastic myelosis, and hemorrhagic aleukia (aplastic anemia). Blood studies showed impoverishment of the 3 blood elements, i. e., isochromic anemia (red blood cells, 1,840,000 per cubic millimeter), leukopenia, and neutropenia, and an absence of platelets. Cold autoantibodies were also demonstrated. The diagnosis of leukosis was eliminated by the myelographic picture, which was practically normal, revealing an abundance of myeloid cells that contrasted strangely with the peripheral pancytopenia. The discrepancy between the findings in the peripheral blood and the appearance of the bone marrow suggested the existence of hypersplenism, and the reduction of formed elements in all 3 blood lines completed the picture of primary splenic pancytopenia, as described by Doan and Wright.

Repeated transfusions, associated with vitamin K, vitamin B_{12}, iron given intravenously, and hormone therapy, failed to produce any lasting improvement, and the patient's condition grew steadily worse until at last splenectomy seemed to be the only means by which her life could be saved. The red blood cell count at this time was 1,580,000 per cubic millimeter and the leukocyte count was 9,600 per cubic millimeter. Energetic measures were taken, with the help of the Blood Transfusion Center, to improve this picture and to prepare the patient for the strain of operation. Transfusions of concentrated plasma increased the number of red blood cells per cubic millimeter to 4,250,000 by the end of 10 days, although the leukocytes numbered only 2,800 and the platelet level fell to 0. The operation was performed 5 days later and was followed by immediate cessation of hemorrhage and a rapid increase in the levels of platelets and the red and white blood cells. The patient left the service in excellent condition about a month after the operation: her skin and mucosa were normal in color; her temperature was 37 C (98.6 F); and she had already started to gain weight. Follow-up 3 months and 8 months later showed that the cure was apparently permanent and that she had every indication of perfect health, both clinically and biologically, although a few autoantibodies had reappeared in the blood.

An anatomicopathological study of the excised spleen revealed only discrete nonspecific lesions of a congestive character, without hemosiderotic overloading or fibrosis. Findings such as these obtained in this case are rare: they bring up the problem of the complex physiopathological mechanism governing the interaction of the spleen and the bone marrow, concerning which much uncertainty still exists. The theoretical aspects of this problem, however, interesting as they are, are eclipsed in practical importance for the clinician by its therapeutic implications. Primary splenic pancytopenia is one of the best indications for splenectomy, and this procedure should be resorted to without hesitation, even in apparently hopeless cases, if hormone therapy has been tried and proved unsuccessful.

Value of Laparoscopy in Ascitic Syndromes Presenting Diagnostic Difficulties. M. Girard and M. Coulot. Semaine hôp. Paris 34:2109-2115 (Sept. 4-12) 1958 (In French) [Paris].

Laparoscopy can now be more widely used because of the modern technical advances which have made the present-day laparoscope a highly developed and only slightly traumatizing instrument. Most French publications describe its value as a diagnostic procedure in conditions affecting the liver and gallbladder, especially jaundice, but this report is concerned with its use in patients with ascitic syndromes. The optical system of the laparoscope, unlike that of the cystoscope, is not designed for looking through liquids, particularly not ascitic fluid, which is rarely clear and transparent. The first requirement, then, is to evacuate the fluid and to dry the peritoneal cavity as completely as possible. This may be difficult, and, if it cannot be accomplished, the projected examination of the abdominal organs may become impossible. The second step is the creation of a pneumoperitoneum through the trocar used in evacuating the ascites. Anesthesia is then induced, plane by plane, with particular attention to the deep peritoneal plane. The small incision needed for the introduction of the trocar and the laparoscope is made with a bistoury at a site determined by the clinical conditions. The transmuscular route is preferable, provided that the course of the epigastric artery is respected, to the median aponeurotic route, which favors the development of postoperative ascitic fistulas. The Fourès laparoscope (diameter, 0.5 cm.), used by the authors, requires only a slight aperture in the muscle, which can easily be closed after the examination with 1 or 2 clips. A drop of collodion over the puncture-insufflation opening completes the operation, which is entirely benign and can be repeated 2 or even 3 times in the same patient.

The diagnostic value of this procedure was amply demonstrated in 32 patients with ascites studied by the authors, who summarize its advantages as follows: 1. Laparoscopy has a threefold importance in the diagnosis of hepatic sclerosis. First, it may show that the sclerosis is due to some cause other than alcoholism, e. g., by revealing the characteristic appearance of the hemosiderotic liver or of the macronodular liver of postviral sclerosis, or, as in one of the authors' patients, the presence of constrictive perihepatitis. Second, the general view of the liver parenchyma obtained by laparoscopy usually provides a better indication of the prognosis than any other clinical or histological guide. Third, laparoscopy alone makes it possible to deny, confirm, or reveal the existence of associated lesions, especially cancer or tuberculosis. 2. Laparoscopy alone in patients with ascites of tumoral origin but no perceptible tumor makes it possible to identify the true cause of the clinical picture (visceral cancer with or without peritoneal extension, primary or especially secondary cancer of the liver, or genital tumors in women). 3. Laparoscopy, supplemented when necessary by biopsy, is invaluable in establishing a diagnosis of peritoneal tuberculosis, sometimes showing the point of origin to be in the adnexa and indicating the type of treatment needed, whether medical or surgical.

Kidney Transplantation Between Seven Pairs of Identical Twins. J. E. Murray, J. P. Merrill and J. H. Harrison. Ann. Surg. 148:343-359 (Sept.) 1958 [Philadelphia].

The total experience with kidney transplantation at the Peter Bent Brigham Hospital in Boston is reviewed. In 16 of the 23 operations the donors were unrelated, and in none of these the transplanted kidney survived permanently. Fifteen pairs of monozygotic twins were observed as potential candidates for renal transplantation, and 7 received transplants from their identical twins. Four of these patients had chronic glomerulonephritis, 1 had subacute glomerulonephritis, and 2 had chronic pyelonephritis secondary to calculus disease and megaloureters respectively. Eight patients did not receive transplants; 3 of these died prior to treatment and testing, 4 still responded to standard therapy, and 1 refused to be considered.

The histories of the 7 patients in whom transplantation was performed are presented. Indications for the transplantation are that the healthy potential donor must have evidence of normal renal function bilaterally, be free from infection, have a normal lower urinary tract, and have sufficient understanding of the significance of a unilateral nephrectomy. The recipient must be in a terminal state of irreversible uremia and have a normally functioning lower urinary tract. The operative technique consists of 2 simultaneous operations, the nephrectomy and the transplantation, being started in 2 adjacent operating rooms. The nephrectomy on a healthy donor requires careful dissection of the vasculature to obtain maximum length of the renal artery and vein. The transplantation is accomplished with the patient under continuous spinal anesthesia. The recipient site is prepared in the right lower quadrant retroperitoneally, exposing the iliac vessels from the bifurcation of the aorta to the inguinal ligament. All the terminal branches of the hypogastric artery are dissected, care being taken to preserve each branch for possible use if renal anomalies are encountered in the donor. The renal artery is anastomosed end-to-end to the hypogastric and the renal vein end-to-side to the external iliac vein. If 2 or 3 renal arteries are present, suitable branches of the hypogastric are selected. The ureter is passed through a muscular tunnel and sutured to the bladder mucosa. The time lapse from clamping of blood supply in the donor to its restoration in the recipient has been 55 to 75 minutes.

Six of the 7 patients obtained return of normal function clinically, chemically, and by x-ray. One of these patients died 4 months after transplantation when the transplanted kidney became involved with the original disease. One other, still living, had signs and symptoms suggestive of active disease in the transplant. Four others are living and well, the longest 3½ years after transplantation. One recipient successfully completed a normal pregnancy a year and a half after transplantation.

NEUROLOGY & PSYCHIATRY

Papillary Carcinoma of the Choroid Plexus. J. Ribe Portugal and E. Geiger. J. Brasil. neurol. 9:91-111 (Jan.-Dec.) 1957 (In Portuguese) [Rio de Janeiro].

Tumors of the choroid plexus are extremely rare in children. As a rule, they are malignant. The treatment consists of surgical removal of the tumor and of roentgenotherapy. The surgical prognosis is poor. Recurrences are frequent and occur shortly after the operation in a high percentage of cases. The authors report the case of a child, 6 years old, who was hospitalized at the Hospital of the Instituto de Neurologia of the University of Brazil with an illness of 2 months' duration. The patient complained of frontal headache and vomiting. On hospitalization he was semicomatous and showed clinical and roentgenologic signs of intracranial hypertension, cerebellar symptoms, and sporadic clonic movements of the hands. The ventriculograms showed a tumor deeply located in the region of the left lateral ventricle. At operation the tumor was found in this ventricle, infiltrating and perforating the cerebral cortex at its middle line and spreading over the lamina quadrigemina and the superior cerebellar peduncles. After the tumor had been completely removed, histological examination showed it to be a papillary carcinoma. The patient did well after the operation and was discharged in satisfactory condition 2 months afterward.

According to the literature on tumors of the choroid plexus in children, these tumors have been located in the lateral ventricles in 32 of the 42 cases reported. The left lateral ventricle was more frequently involved than the right. Of the 42 cases, the tumor was found at autopsy in 24; 8 patients died postoperatively, and 10 recovered from the operation. One of the patients who recovered was a 6-year-old child. He is well and without any signs of recurrence 4 years after the operation. This case from the literature is similar to the one reported by the authors.

The Diagnosis and Treatment of Non-Traumatic Cerebrovascular "Accidents": With Special Emphasis on Intracranial Hemorrhage and the "Common Stroke." M. Scott. Pennsylvania M. J. 61:1190-1197 (Sept.) 1958 [Harrisburg].

Cerebrovascular accidents are fourth among the causes of all deaths (170,000 cerebrovascular deaths in 1952), and many more persons are partially or totally disabled by such accidents. The author defines a stroke as a symptom-complex that is most frequently caused by cerebral hemorrhage, thrombosis, embolism, or a brain tumor. The treatment depends upon the differential diagnosis, which can be reached by the following studies: careful history; physical and neurological examination; examination of the eyegrounds and perimetric fields; examination of the spinal fluid for pressure, color of fluid, cell count, quantitative protein, and Wassermann reaction; x-rays of the skull for evidence of shift of the pineal gland; and finally, after careful deliberation, cerebral angiography to decide between intracranial hemorrhage, vascular occlusion, and a brain tumor. Many persons with strokes due to small cerebral hemorrhages or thrombosed vessels recover spontaneously. The intramuscular administration of papaverine hydrochloride in doses of 100 to 200 mg. 4 times a day or the inhalation of 5 or 10% carbon dioxide in 95 or 90% oxygen is preferred treatment for cerebrovascular occlusion or embolism. The use of anticoagulants for suspected thrombosis can cause harm if hemorrhage is confused with thrombosis. Bleeding must be ruled out by a careful history, absence of hemorrhage in the eyegrounds and spinal fluid, and normal position of the pineal gland. The same precautions apply to the use of anticoagulants in cerebral embolism, but here they seem indicated.

The value of stellate block is uncertain. It should be done within 12 hours after the stroke by one skilled in its use and should be repeated 3 or 4 times at 12-to-24-hour intervals. Patients with cerebral aneurysm causing intracranial hemorrhage can be helped sometimes by ligation of the common or internal carotid artery in the neck or intracranial clipping of the aneurysm. Occasionally, patients with massive hemorrhages of the brain can be helped by prompt surgery with evacuation of the clot. The treatment should include therapy of the paralyzed extremity, treatment of speech defects, and management of the individual as a whole for ambulation and livable life.

GYNECOLOGY & OBSTETRICS

Myocardial Failure in Toxemia of Pregnancy. P. N. Siliquini and G. Garbagni. Minerva ginec. 10:531-535 (July 31) 1958 (In Italian) [Turin, Italy].

The correlation between electrocardiograms and tissue oxygen utilization tests was studied in 53 patients with toxemia of pregnancy during the last trimester of pregnancy. The concurrent symptoms of the toxemia of pregnancy were edema, albuminuria, and hypertension. The degree of severity of the disorder was rated on the basis of deficiency in tissue oxygen utilization. Toxemia of pregnancy was rated as mild if the values of the tissue oxygen utilization test varied between 20 and 16%. In this group there were 23 women with a systolic pressure of 160 to 195 mm. Hg and a diastolic pressure of 90 to 105 mm. Hg. Electrocardiographic patterns did not change significantly during this moderate phase, as compared with those recorded before and after the clinical manifestation of the disease. Only a slightly increased cardiac frequency and moderate signs of a greater load on the left ventricle were observed. Toxemia of pregnancy entered a more severe phase when the values of the tissue oxygen utilization test varied between 15 and 11%. This condition was found in 18 patients with a systolic pressure of 150 to over 200 mm. Hg and a diastolic pressure of 95 to 135 mm. Hg. Electrocardiographic patterns showed changes due to the state of pregnancy or to the arterial hypertension in 11 patients. Myocardial failure characterized by smoothing of the 5T segment and flattening of the T wave in all leads was observed in the electrocardiograms of 7 patients.

Toxemia of pregnancy was rated as very severe if the values of the tissue oxygen utilization test varied between 10 and 8%. These values were found in 12 patients, in whom a high degree of edema, albuminuria, and hypertension was observed. The systolic pressure of these patients ranged from 175 to 230 mm. Hg, and the diastolic pressure from 105 to 145 mm. Hg. Ten patients had episodes of eclampsia. Electrocardiographic patterns revealed the presence of diffuse myocardial failure during the acute phase of the disorder in 8 patients; they showed normalcy when the symptoms of toxemia subsided. Decompensation of the left ventricle was established in 3 patients. Since there was no evidence of heart disease in their past history, the decompensation was interpreted to be a manifestation of myocardial failure in toxemia of pregnancy. The decreased tissue oxygen utilization seemed to have been the main pathogenic factor of myocardial failure in this series of patients.

Uterine Carcinoma of Gartner Duct Origin. J. J. Andujar and F. E. Council. Texas J. Med. 54:658-662 (Sept.) 1958 [Austin].

The authors report on 2 women, aged 20 and 25 years, with carcinoma of the uterus originating from Gartner's duct remnants in the organ. Both patients had a persistent vaginal discharge, and both were sterile. A large biopsy specimen was obtained from the younger patient, and a diagnosis of granuloma of the histiocytic type was made. Although the complete lack of mucin and the large, foamy, pinkish cells with an occasional cart-wheel appearance should have given a clue as to the nature of the lesion, an effort was made to cauterize the lesion on the right lip of the uterine cervix, and the patient refused further treatment. She died 8 months after the biopsy was performed, and autopsy was refused. Hysterectomy was performed on the second patient. The surgical specimen showed that the tumor occupied most of the cervix and endocervix and that it seemed to merge with the contiguous musculature of the uterus. Microscopic examination revealed large cells of a rather pinkish color, with round or polyhedral edges. The nuclei were pale and slightly vesicular. In occasional rare fields one could see a cart-wheel pattern. There was no mucin elaborated. No evidence of metastasis was observed 3 years after the surgical intervention.

Gartner's duct remnants in the uterus may give rise to neoplasms. There is a wide difference in the reported incidence of such remnants. Of 1,716 uteri removed by complete hysterectomy and examined by the authors in an attempt to determine the incidence of these remnants by step sectioning the cervix and its vaginal portion horizontally at intervals of a few millimeters, reasonably characteristic Gartner's duct remnants were found in only 36, an incidence of almost 2%. A deceptive microscopic pattern and a lack of awareness of carcinoma of the uterus originating from Gartner's duct remnants may lead to an erroneous diagnosis. The benign appearance of the carcinoma was belied by its fatal course in the first patient. It is possible that the second patient was cured as a result of early removal of the uterus with tubes and ovaries, but survival for 3 years does not warrant a cure. Most of the patients whose cases were collected from the literature later had metastases and died despite the innocent appearance of the histological pattern of the tumor. This type of carcinoma of the uterus deserves far more attention and consideration from clinicians and pathologists in order to classify and combat it effectively and accurately.

Endocrine Relationships between Chronic Cystic Mastitis and Cancer of the Breast. N. A. Womack. Am. Surgeon 24:618-629 (Sept.) 1958 [Baltimore].

This report is based on an extensive review of the literature and on observations made in the department of surgery, University of North Carolina School of Medicine, and the North Carolina Memorial Hospital at Chapel Hill. The hormones having the greatest effect on breast structure are the estrogens, progesterone, and the lactogenic principle from the hypophysis, prolactin. In the breast these hormones work both synergistically and antagonistically. The numerous breast lesions that have come to be referred to as chronic cystic mastitis all represent variants of a single group of histological changes, e. g., duct growth as evidenced by epithelial hyperplasia, duct branching and increase in diameter, acinar atrophy, and periductal edema and fibrosis. At times there may be secretion within the duct; at times there is also round-cell infiltration. The dominant lesion, however, remains within the duct. Thus, it can be seen that chronic cystic mastitis has little to do with inflammation and frequently is not related to cysts. The term "chronic cystic mastitis," however, has reached such a fixed state in medical nomenclature that the author does not attempt to change it. Chronic cystic mastitis develops when a factor of initial susceptibility is followed by a period of long and constant uninterrupted estrogenic action Chronic cystic mastitis is a conditioned proces when not associated with permanent epithelia change. It is thus reversible, and this reversion ca be brought about by the withdrawal of estroge or the administration of an estrogen antagonist Progesterone in adequate dosage seems to be a effective antagonist.

At the author's clinic progesterone in oil wa used in treating 15 patients with chronic cysti mastitis. Pure progesterone in oil was given intra muscularly in 50-mg. doses, beginning about weeks after the start of the previous menstrua period and on alternate days until the next perio began. The use of progesterone in oil, because i necessitated several injections each month an was expensive, was not satisfactory. Neither wa long-acting testosterone which, while an effectiv antiestrogen, possessed undesirable side-effect More recently at the author's hospital hydroxypro gesterone caproate (Delalutin) has been used. Thi progesterone ester is given as a single intramuscula injection of 250 mg. The results obtained with it i 41 patients are tabulated. After 3 or 4 successiv monthly injections treatment is stopped, and th patient is examined at intervals of 3 months. I cysts recur, a new cycle of treatment is begun. Al treatment can usually be stopped after the meno pause. Most patients treated with either hydroxy progesterone caproate or progesterone in oil re sponded favorably to 3 or less monthly injection the premenstrual breast pain and the nipple dis charge being relieved. These observations, alon with the fact that the cysts did not refill unde therapy, suggest an effect on duct secretion. It i also of interest that 17 of the 56 patients treate had had previous surgical excision of the cystic disease before beginning hormone therapy.

The promoting factor for chronic cystic mastitis, namely, estrogen, also promotes the progression of breast cancer. If the initiating factor for the latter happens also to be present in a patient with chronic cystic mastitis, progression into cancer may occur. Statistical evidence suggests that women with chronic cystic mastitis stand a greater chance to develop breast cancer than do women without it. When cancer of the breast occurs, the withdrawal of sources of endogenous estrogens or the administration of antagonists, such as androgens, will be effective only to the extent to which the cancer cells are reversible.

PEDIATRICS

Ulcer Disease in Children. C. C. Hatfield. Virginia M. Month. 85:561-564 (Oct.) 1958 [Richmond].

The author presents the histories of 2 girls, aged 9 and 13 years, and of 2 boys, aged 14 and 17 years, who had a variety of abdominal symptoms and in whom investigation revealed duodenal ulcer. The children were observed in the course of less than

13 months. The 9-year-old girl exhibited typical ulcer symptoms, and the author feels that had she been 20 instead of 9, a diagnosis would have been made at the first office visit. The 13-year-old girl offered a more difficult problem since her symptoms were vague; she resembled the adult patient, with mild epigastric distress and vomiting without definite physical findings. The 17-year-old boy had an almost classical picture except for absence of relief by food; his symptoms were all referable to his gastric retention. The 14-year-old boy had typical ulcer symptoms for 2 years, with retention being the outstanding cause of complaint.

Ulcer disease in children presumably runs the same course as in adults. There is pain, hypermotility, gastric retention, food relief, flatulence, nausea, and vomiting. In the children of this series fluoroscopic examination proved of greater value in identifying the site than did the conventional plates. The use of a spot-film device aids in capturing the involved area at critical moments. It is well to remember that ulcer disease may appear at any age. Symptoms and signs are the same in children as in adults. Response to treatment is excellent. If the physician is aware of the possibility of ulcer disease in children and keeps it in mind, he will be able to diagnose the condition in many of these patients earlier and rehabilitate them more quickly.

The Incidence of True, Chromatin-Positive Klinefelter's Syndrome and Its Relationship to Feeblemindedness. A Prader, J. Schneider. W. Züblin and others. Schweiz. med. Wchnschr. 88:917-920 (Sept. 20) 1958 (In German) [Basel, Switzerland].

The authors determined the nuclear pattern of sex in 336 boys, between the ages of 7 and 15 years, with mild feeblemindedness who attended special classes of the city school in Zürich, Switzerland, and in 390 boys with a high degree of intelligence who attended various high schools in eastern and central Switzerland and served as controls. Of the 336 boys in whom the nuclear pattern was determined with the aid of buccal smears, 8 were found to be chromatin-positive, i. e., their nuclear pattern was of the female sex but they were phenotypic males. The nuclear pattern of the leukocytes was also female in these 8 boys. These findings were sufficient for the diagnosis of true Klinefelter's syndrome. There was no doubt as to the correctness of this diagnosis, since the 2 oldest of the 8 boys had already reached puberty and showed the classic triad of this syndrome, namely, small testes, gynecomastia, and increased excretion of gonadotropin in the urine. Not a single one of the 390 high-school boys with high intelligence was found to be chromatin-positive.

The incidence of true Klinefelter's syndrome was estimated by other workers to be 1 in 10,000. In contrast to this estimated incidence, the authors' findings suggest an incidence of 1 in 42 in males with mild mental deficiency and of at least 1 in 1,000 in the entire male population, i. e., an incidence 10 times higher than the estimated one. The authors' findings prove that the previously observed frequent occurrence of mild feeblemindedness in patients with true Klinefelter's syndrome is not an accidental one. It justifies the routine determination of the nuclear pattern of sex in all mentally deficient males. Due to the fact that 6 of the 8 boys had not yet reached puberty, it was possible to study for the first time the somatic, electroencephalographic, and psychopathological aspects of the true Klinefelter's syndrome in childhood. Similar to the observations made in adult patients with this syndrome, 2 types of body build were seen in the prepuberal patients, namely, the type with inconspicuous proportions of the body and that with definitely eunuchoid proportions. The psychopathological aspect of mild feeblemindedness, mental infantilism, and passive personality was quite similar to that observed, as a rule, in adult patients. A marked psychoendocrine syndrome which was reported frequently in adult patients was apparently absent in the prepuberal patients. Abnormal electroencephalographic recordings were obtained from 4 of the 6 prepuberal patients.

Influence of Adrenal Cortical Hormones on the Course of Miliary Tuberculosis. A. Nitschke. Deutsche med. Wchnschr. 83:1593-1595 (Sept. 12) 1958 (In German) [Stuttgart, Germany].

Earlier observations had revealed that glucocorticoids, such as cortisone, exert a favorable influence on tuberculous meningitis in childhood in that the sugar and chloride contents of the cerebrospinal fluid, which otherwise are reduced for periods of many weeks and which under the influence of tuberculostatic drugs increase only gradually, are elevated to a normal range within a few days after cortisone is given as an adjuvant. The increase in the sugar content of the cerebrospinal fluid can serve as a guide not only for the size of the cortisone dosage but also for the period cortisone treatment has to be continued so that the normalized sugar level will not decrease again.

The author used cortisone or prednisone in treating 9 children with miliary tuberculosis, of whom 4 had miliary tuberculosis without meningitis. It was found that the drugs had to be given over long periods and in large amounts. Doses of 3 mg. of prednisone per kilogram of body weight per day caused regression of the miliary foci in the lungs within an average of 20 days after the onset of treatment, so that they were no longer visible on roentgenoscopy. At the same time, the general condition, the fever, and the sedimentation rate of the erythrocytes were favorably influenced. Comparable series of children treated earlier only with streptomycin and isoniazid showed a similar regression of lesions much later, generally after more than 3 months. In children in whom meningitis complicated the miliary tuberculosis, the meningitis usually subsided simultaneously with the miliary lesions, as was indicated by the sugar and chloride values of the cerebrospinal fluid. In children with miliary nodules in the eyegrounds (retinal involvement), the signs of acute inflammation rapidly regressed, leaving minute scars. The acceleration of the healing processes was so striking that the use of corticosteroids as adjuvants is recommended, provided that proper precautions are taken.

Pulmonary Atelectasis in Bronchial Asthma in Children. J. Luhr. Nord. med. 60:1198-1199 (Aug. 21) 1958 (In Norwegian) [Stockholm].

Pulmonary atelectasis refers to roentgenographically demonstrable collapse of larger or smaller parts of one or both lungs. It is a relatively frequent complication in bronchial asthma in children. Roentgenograms of the lungs of 217 children with bronchial asthma who were treated in the Children's Clinic of the Rikshospital in 1951-1956 showed atelectasis in 12 children, most of them under 10 years of age. It was localized in one lobe, usually the middle lobe of the right lung. Roentgenologic clarification occurred after from 12 to 77 days. Three patients had relapses which persisted for 6, 19, and 106 days respectively. True allergy was seen in 7 patients; bacterial allergy, in 5. Atelectasis may occur in symptom-free periods but occurs more often during asthma attacks. It is ascribed to occlusion of one or more bronchi because of abundant, thick, tenacious secretion, edema of the bronchial mucous membrane, and spasm of the bronchial musculature. The prognosis seems to be good. Bronchoscopy with aspiration of secretion, and possibly the administration of antibiotics to prevent a secondary infection, may be necessary if the atelectasis does not recede quickly.

THERAPEUTICS

A New Superior Oral Diuretic Drug, Chlorothiazide (Diuril): Clinical Evaluation. G. R. Herrmann, M. R. Hejtmancik, R. N. Graham and R. C. Marburger. Texas J. Med. 54:639-644 (Sept.) 1958 [Austin].

Fifty hospitalized patients with congestive heart failure and other diseases involving edematous and hypertensive states were treated with chlorothiazide (Diuril), a sulfamyl benzothiazide compound. The patients were on a low-salt diet (100 mg. per day), and most of them received 45 mEq. of potassium per day. At first, 250 mg. of chlorothiazide was given orally 1, 2, 3, or 4 times a day, and then the dose was gradually doubled for a total of 1 to 2 Gm. per day. The average 24-hour dose in these 50 patients was 750 mg. because of the low dosage used at the beginning of the therapeutic trial. At present 1.5 to 2 Gm. per day is given, and no toxic reaction has occurred, except for a mild rash in patients, diarrhea in 1 patient (which may hav been incidental), and hypopotassemia in 2 patients

Chlorothiazide given orally in doses of 1 to 2 Gm daily practically always initiated a diuresis withi 1 or 2 hours, to reach a maximum at 4 hours and t continue for another 12 to 24 hours. The averag duration of therapy in this group of patients wa 14½ days, with a maximum of 66 days and a minimum of 2 days. The urinary output before the institution of treatment with chlorothiazide average 1,120 cc. per day, as compared with an average output of 1,725 cc. per day after the administration the drug. The loss of weight in these patients ove the average 14½ days of treatment was 15½ lb. (7 kg.). The output of the urinary electrolytes was quadrupled freqently in the first few days of chlorothiazide therapy. It then was maintained at doubled values for 5 to 7 days and remained elevated as long as the urine flow was increased. The patients in congestive failure excreted on the average 28.75 Gm. of sodium, 35.03 Gm. of potassium, and 29.5 Gm. of chlorides for the diuretic period averaging 14 days. The potassium output was unduly high as a result of the routine loading of potassium chloride.

Chlorothiazide thus proved to be highly effective in the treatment of edema. It is ideal for long-term therapy in patients with congestive heart failure except for those on a low-sodium diet and for those with hypertension, nephrosis, and cirrhosis. It may produce low serum potassium levels, and it seems desirable to administer 4 Gm. of supplementary potassium chloride daily, especially if digitalization or steroid administration is carried out. Chlorothiazide is particularly effective in patients with hypertensive atheromatous coronary ischemic heart disease associated with edema, and the drug is superior to all other diuretics, including organic mercurial preparations given by the parenteral route. Chlorothiazide is the drug of choice in eclampsia and in edema of pregnancy. Chlorothiazide appears to be the safest, most effective, and most practical diuretic that has been added to the armamentarium since mercaptomerin (Thiomerin) was introduced.

Experiences with Chlotride, an Orally Administered Nonmercurial Diuretic Used for Treatment of Cardiac Edema. R. Richterich. Schweiz. med. Wchnschr. 88:906-910 and 931-934 (Sept. 13 and 20) 1958 (In German) [Basel, Switzerland].

Chlotride is the Swiss trade name for chlorothiazide (Diuril). This new diuretic sulfonamide with mercurial-like action is administered orally and enhances particularly the sodium and chloride excretion without producing any change in the excretion of bicarbonate in the urine. Often a slight increase in the urinary excretion of potassium may be observed. Three women and 2 men, between the ages of 54 and 81 years, with acute congestive heart failure and extensive edema, 2 of whom were resistant to mercurial diuretics and acetazolamide (Diamox), were given orally 1 Gm. of chlorothiazide per day. Good diuretic results were obtained in all the patients. Undesirable side-effects were observed in only one patient who vomited once on several days; this patient also had a mild degree of hypochloremic alkalosis and showed signs of overdosage of digitalis (bigeminy) which disappeared spontaneously within 24 hours.

Thirteen additional patients with chronic decompensation of the right heart received alternately for 8 to 12 days 3 Gm. of ammonium chloride daily combined with 1 cc. of mercaptomerin (Thiomerin) once a week, and 500 mg. of chlorothiazide given twice a day. The diuretic effect obtained by these 2 methods of treatment was about the same, but resistance to chlorothiazide did not develop and chlorothiazide did not cause any side-effects. At present chlorothiazide is considered the diuretic of choice for the treatment of cardiac edema, because it can be administered orally, its diuretic action is satisfactory, and undesirable side-effects occur only rarely.

Clinical Experiences with the Anticoagulant Warfarin Sodium ("Coumadin Sodium").

R. R. Porter, D. Richardson and H. Page Mauck Jr. Virginia M. Month. 85:465-471 (Sept.) 1958 [Richmond].

The authors report a study on 80 patients with various thromboembolic disorders who have been treated with warfarin (Coumadin) sodium during the last 2 years at the McGuire Veterans Administration Hospital and the Medical College of Virginia Hospital in Richmond. The initial "priming" dose of Coumadin varied from 25 to 75 mg. as a single dose and from 50 to 100 mg. as a double dose administered orally, and from 50 to 60 mg. as a single dose administered intravenously. The sensitivity of patients to Coumadin varies from individual to individual, but it is fairly constant in the same patient. It would appear that a standard dose of 50 to 60 mg. will be suitable in the vast majority of patients weighing between 60 and 80 kg. (133 and 177 lb.) and having initial prothrombin activities of from 60 to 100%. If the patient is unusually heavy or obese, the dose can be increased to 75 mg. The dose should be reduced for patients weighing less than 60 kg. if the initial prothrombin time is 50% or less and if heparin in significant amounts (more than 300 mg. intramuscularly or 150 mg. intravenously daily) is given concomitantly to achieve some measure of anticoagulation during the latent period, i. e., from the time of administration of Coumadin and the onset of therapeutic effects.

The fairly rapid and consistant hypoprothrombinemic effect of Coumadin as measured by the Quick one-stage method confirms the findings as previously reported by other authors. After the initial latent period of from 12 to 18 hours, there is a rapid decline in prothrombin activity, with therapeutic levels attained in 24 to 36 hours after administration. Within the dose range of 50 to 75 mg. there was little difference in the achievement of a therapeutic effect in this 24-to-36-hour period, regardless of the patients' weight. After initial and prompt anticoagulation effect with Coumadin, maintenance therapy can be instituted. The response to the initial dose will be an indication of the patients' sensitivity to Coumadin and will serve as a guide for subsequent maintenance therapy. After 2 or 3 days of adjustment a smooth maintenance is usually achieved on relatively constant dosage, depending on the therapeutic response. Small daily doses achieve smoother control than intermittent larger doses. Coumadin is free of toxic side-reactions, the only adverse effects being its pharmacological action leading to excessive hypoprothrombinemia from overdosage. This latter is readily counteracted by the administration of a single dose of 50 mg. of vitamin K_1. Coumadin appears to be superior to all other hypoprothrombinemia-inducing agents currently available and seems to be the drug of choice for anticoagulant therapy in thromboembolic disorders.

Treatment of Intermittent Claudication with Vitamin E.

P. D. Livingstone and C. Jones. Lancet 2:602-604 (Sept. 20) 1958 [London].

The authors report on 40 nondiabetic male patients with obliterative vascular disease who complained of intermittent claudication. Symptoms had been present for at least 5 years, and in all the patients the pain was felt in the calf muscles. Twenty of the 40 patients were treated with vitamin E and 20 were given placebos. The average age of the patients who received vitamin E was 55.9 years and that of the control group, 57 years. There were 3 patients, aged 40 to 50 years, in each group. A full general examination, with particular attention to the lower limbs, was carried out. Bilateral femoral arteriography showed pronounced arteriosclerotic changes and occlusion. Exercise tolerance tests were performed by climbing up and down a series of 2 steps, 18 in. high, until pain made the patient stop. The results of these tests were evaluated by the patients' own assessment and by the improvement in the average number of circuits (climbing up and down the steps) in the course of the treatment. Treatment was discontinued in 3 patients of each group. Four of the 17 patients who remained in the group treated with vitamin E did not respond at all to treatment. The remaining 13 patients showed much improvement; 7 were able to continue walking indefinitely at a slightly slower pace than usual, 4 were able to walk any distance of up to half a mile and do their full work, and 2 showed slight, but definite, improvement judged by the increase in the number of circuits and steps, and the patients were quite certain that they were more active than they had been and that the pain was less severe. Two of the patients in the control group recovered sufficiently to walk a useful distance. One of these, for no apparent reason, made a complete recovery after suffering from severe claudication for many years. All the other patients in this group derived no appreciable symptomatic relief. Six months after the end of the trial, none of the treated patients, who had improved, had deteriorated; and 3 patients in the control group, who had been transferred to vitamin E therapy at the end of the trial, reported some improvement.

Observations on Peroral Therapy for Diabetes. E. Ikkala and W. J. Kaipainen. Ann. med. int. Fenniae 47:63-73 (No. 2) 1958 (In English) [Helsinki].

Peroral therapy was adopted at the end of 1955 in the outpatient department of the University of Helsinki for 22% of the 675 patients with diabetes who attended the clinic regularly. Peroral treatment with BZ 55 (Alentin) or D 860 (Diabuton) was given to 147 diabetics. In selecting patients for this therapy, mostly older obese diabetics were chosen. The treatment was not given to juvenile diabetics, to patients using large quantities of insulin or those receiving this drug for more than 10 years, and to patients predisposed to ketonuria. Of the 147 diabetics, 27% were fresh cases (no dietary or insulin therapy for more than a month), 43% had been earlier on dietary therapy, and 30% had been earlier on insulin therapy. Seventy-nine per cent of the perorally treated group were women. More than half of the cases were followed up for over a year.

A distinctly better blood sugar equilibrium was generally established with the peroral drugs in the group of fresh cases (40 patients) and in the 63 patients earlier on dietary therapy. Of 459 insulin-treated patients under observation, a switch to peroral therapy was made in the case of 61; in 44 patients the peroral drugs could be substituted for insulin, but in 9 (some of these did not meet the requirements for selection) they were ineffective, and in 8 they were withdrawn for other reasons. Insulin therapy was thus replaced by peroral therapy in 9.6% of the cases.

A weight gain, especially among diabetics earlier on dietary therapy, was observed in spite of a warning to the patients that they should follow previously issued dietary instructions. Of 33 patients who were started on peroral therapy but had to discontinue it, 6 were clearly outside the category for selection; the therapy was considered unnecessary for another 6 patients and was discontinued for 10 at their own request, although no detrimental side-effects were demonstrable. The peroral therapy had to be terminated because of ineffectiveness in 8 patients, who had shown all indications for successful treatment, and in 3 because of allergic reactions to BZ 55. Ineffectiveness of the peroral treatment usually became evident within a month of experimentation.

Effect of Chlorothiazide on Renal Electrolyte Excretion. U. V. Lassen and O. Munck. Ugesk. læger 120:1112-1115 (Aug. 21) 1958 (In Danish) [Copenhagen].

A single dose of chlorothiazide administered to normal persons was followed by greatly increased secretion of sodium and chloride ions and some increase in bicarbonate and ammoniac excretion The creatinin clearance was not affected. If chlorothiazide is given intermittently on good indication electrolyte disturbance will rarely occur, at al events not in persons on a normal diet. Overdosage of chlorothiazide caused metabolic acidosis, hypokalemia, and hypochloremia.

Chlorothiazide Treatment of 10 Patients with Edema. C. Michelsen. Ugesk. læger 120:1118-1121 (Aug. 21) 1958 (In Danish) [Copenhagen].

The results of chlorothiazide treatment in 11 patients with edema are discussed. Daily examinations of the serum and urine for values of potassium, sodium, bicarbonate, and chloride, determinations of the pH and pCO_2 of the blood, and diuresis were carried out; there was also regular control of the urine for protein, of serum uric acid and creatinin values, and of blood pressure and weight. In one patient treatment had to be discontinued because of hypokalemia. In 3 patients the treatment was without effect. The remaining 7 patients showed increased diuresis and increased excretion in the urine of sodium, potassium, and bicarbonate. In about half of the patients there was a tendency to a low serum potassium level. No essential shiftings in the acid-base conditions were seen in any case. Two patients were treated with chlorothiazide for a longer time.

Local Treatment of Bronchial Asthma with Hydrocortisone Powder. H. Herxheimer, M. K. McAllen and D. A. Williams. Brit. M. J. 2:762-765 (Sept. 27) 1958 [London].

The authors report on 79 patients with chronic bronchial asthma who were treated by inhaling a capsule of micronized hydrocortisone snuff from a powder inhaler. A capsule, containing 15 mg. of hydrocortisone and 85 mg. of lactose, was placed in this inhaler; half of the contents were inhaled in the morning and half in the evening. Forty-five of the 79 patients served as their own controls; a few of the 45 were given hydrocortisone snuff for

2 weeks, followed by a similar period during which hydrocortisone snuff was not given; in most of the 45 patients the hydrocortisone snuff period was followed or preceded by an equal period of placebo snuff. A definite improvement in symptoms occurred in 33 of the 45 patients. This improvement was observed mainly in patients with a history of allergy and in those without hypersecretion. Improvement was seen to a much less extent in patients with the infective type of asthma than in those with the allergic type. Patients with "dry" asthma, i. e., those who never expectorated any mucus except during rare and short periods of upper respiratory infection, responded dramatically. These findings show that the result of topical treatment in any group of patients with asthma will mainly depend on the type of asthma involved. The hope that the topical treatment of bronchial asthma might replace steroid systemic therapy in most cases and might thus avoid the dangers of continuously given large systemic maintenance doses has not materialized; only a minority of patients appear to be benefited by corticoids given topically.

Bronchial Asthma and Chronic Bronchitis Treated with Hydrocortisone Acetate Inhalations. W. H. Helm and F. Heyworth. Brit. M. J. 2:765-768 (Sept. 27) 1958 [London].

Twenty-five male and 28 female patients, between the ages of 15 and 61 years, with asthma or wheezy bronchitis of at least one year's duration, whose condition had been severe enough to necessitate periods off work, were hospitalized and treated with antibiotics and routine antispasmodic drugs before receiving hydrocortisone inhalations. The patients inhaled fine hydrocortisone acetate powder from a "pabracort" inhaler, the powder being in capsules containing 15 mg. of hydrocortisone acetate and 75 mg. of lactose powder, both being ground fine to a mean particle size of 5 μ. The initial dose varied between 1 capsule 3 times a day and 1 capsule daily, given as half a capsule twice daily, according to the severity of the wheezing at the beginning of treatment. The dose was reduced to the minimum maintenance necessary as soon as improvement occurred. The usual maintenance dose was half a capsule twice daily. Treatment was stopped in patients with recurrent asthma, once the attack had been relieved for a week, and they were provided with capsules and instructed to restart at the onset of symptoms in a dose of between 1 and 3 capsules daily according to the severity of the attack. Patients who had failed to make any definite improvement during 2 weeks' treatment with inhalations were assessed as failures, and the treatment was stopped.

Of the 53 patients, 43 (81%) improved on hydrocortisone inhalations, whereas 10 (19%) were not improved. Of the 43 patients who improved, 13 (30%) relapsed after periods of 1 to 11 months, whereas 30 (70%) maintained the improvement for periods varying between 2 months and 2 years. Best results were obtained in patients with recurrent acute asthma without significant bronchial infection, whereas the results in patients with wheezy bronchitis were disappointing. There were no definite complications, but one man had mild dyspepsia for a few weeks, which may have been due to the hydrocortisone. Several patients put on weight, which was probably due partly to improved health and partly to the effects of hydrocortisone absorption.

The inhalations of fine-particle hydrocortisone acetate powder thus were found to be an effective form of treatment in many patients with bronchial asthma. There is a strong tendency to relapse if the treatment has to be maintained, but prolonged benefit may continue if the inhalations can be used intermittently for recurrent attacks of asthma. Although the treatment may be successful in status asthmaticus, it is probably less effective in this condition than intravenous or oral administration of corticosteroid drugs, and its use is not recommended if the patient is dangerously ill. A considerable portion of the "inhaled" hydrocortisone is probably absorbed, but the dosage is low compared with that used in oral therapy with a corticosteroid, and the chance of toxic effect is, therefore, much less. The optimum dosage is uncertain, but it probably varies from patient to patient. Little or no benefit is likely to be obtained from this form of treatment in patients with established chronic bronchitis.

Inhalation of Hydrocortisone Acetate for Bronchial Asthma: A Short-Term Controlled Trial. W. H. Helm and F. Heyworth. Brit. M. J. 2:768-769 (Sept. 27) 1958 [London].

A short-term controlled trial of inhalations of hydrocortisone acetate in fine-particle powder was carried out by the "double-blind" method during 38 trial periods in 14 men and 12 women with bronchial asthma of at least one year's duration. Of the 26 patients, 17 were treated by inhalations of hydrocortisone powder; 14 of these were improved, and 3 were not improved. Of the remaining 9 patients treated by inhalations of a placebo powder, 3 were improved and 6 were not improved. Thus, the number of patients improved in the hydrocortisone-treated group as compared with the placebo-treated group was at a statistically significant level. Hydrocortisone powder inhalations, therefore, are an effective form of short-term treatment in some patients with bronchial asthma.

Nature and Treatment of Septic Shock. W. A. Altemeier and W. R. Cole. A. M. A. Arch. Surg. 77:498-507 (Oct.) 1958 [Chicago].

The survival of 16 patients in a series of 41 with septic shock is indicative of the effectiveness of the basic principles of treatment which have been evolved. The importance of treatment and an early recognition of septic shock cannot be overemphasized. Delay in diagnosis and failure to recognize the septic cause of the circulatory collapse when the process becomes terminal or irreversible are chief factors responsible for failure of therapy. Early diagnosis and treatment will be facilitated if the significance of the characteristic sharp curves of rising temperature, pulse rate, and white blood cell count and the coincident inverted curve of falling arterial pressure and urinary excretion are kept in mind. The fact that only 25% of these patients demonstrated any evidence of hemoconcentration has supported the belief that large amounts of fluid replacement are not indicated and that they may be harmful in producing pulmonary edema if used in a vain effort to restore the blood pressure.

The intravenous infusion of arterenol in 5% dextrose in water has appeared to be particularly useful when regulated to maintain a systolic blood pressure above 80 mm. Hg and a urinary output of 25 cc. or more per hour. By this method it has been possible to maintain urinary function until the infection has been brought under control and to permit survival of the kidneys. Arterenol was administered for periods up to 144 hours to 15 of the 16 patients who survived. It was infused through indwelling polyethylene tubing, thus preventing local cutaneous gangrene. Large doses of intravenously administered antibiotics seemed efficacious in controlling the infection, but 2 to 7 or more days were required for this effect. This delay emphasized the importance of adequate supportive treatment to extend life until the antibiotic effect could be obtained. When arterenol was found to be inadequate, hydrocortisone in doses up to 100 mg. was given to 3 patients; without it, it is doubtful whether any of these patients would have survived. Eleven of the 16 surviving patients received blood or plasma or both, the amounts varying from 500 to 4,500 cc. Thirteen patients were given oxygen therapy over periods of 24 to 168 hours. It is generally better to treat patients with a severe uncontrolled infection conservatively, but surgical intervention may be necessary in those manifesting sudden vascular collapse. It takes critical judgment to determine which patients with septic shock require operation and the time when this is feasible.

PATHOLOGY

Failure to Prove Identity of Tumor Cells in the Peripheral Blood. F. W. Taylor and F. Vellios. Surgery 44:453-456 (Sept.) 1958 [St. Louis].

The concept that there may be occasional showers of cancer cells in the peripheral blood of cancer patients is not new, and interest in this problem was revived by a monograph published by Engell in 1955. The authors felt that one means of definitely establishing the identity of such cells would be to reinject the suspected cells in the hope of producing a metastasis. Four patients were studied who were in the terminal phase of neoplastic disease. All had carcinoma (of lung, stomach, or colon) with widespread extension; "tumor cells" were demonstrated in the peripheral blood of each. The patients died at intervals of 2 to 7 months after the investigation.

In carrying out the investigation, blood was drawn from the antecubital vein into a heparin solution or was taken from the femoral artery. The blood was then spun for 15 minutes at 1,500 rpm so that a buffy coat could be isolated. This layer was mixed with a small quantity of isotonic sodium chloride solution to make approximately 2 ml. This mixture contained most of the suspicious abnormal cells present in a 50-to-80-ml. sample of the patient's peripheral blood. Twelve such samples were withdrawn from the 4 patients. The buffy coat mixture was reinjected into the patient from whom the sample was taken, usually into a marked area of subcutaneous fat or muscle, but on some occasions it was given intradermally as well. The injection resulted in a local lump, which was observed to diminish in size until no palpable nodule was present 2 months after injection. After death the tissues at the injection site showed little or no gross abnormality. Under microscopic examination there were a little fibrosis, hemosiderin, foreign-body giant cells, and occasionally nuclear fragments. There was, however, never any evidence of tumor cells at the site of injection. No secondary tumor growth resulted.

The authors feel that this failure to reproduce tumor growth from suspected tumor cells in the peripheral blood stream neither proves nor disproves them to be circulating cancer cells. Reasons suggested why these cells might not reproduce a secondary lesion include that the number injected was probably comparatively small and that they were injected with huge numbers of leukocytes. As this mass of leukocytes undergoes degeneration, various ferments are liberated which are highly detrimental and lytic to all cell protoplasm. The tumor cells might well be lysed as a result. Furthermore, the host must have the ability to eliminate stray tumor cells, for otherwise metastases would be unlimited. The elected sites of injection (skin, subcutaneous fat, and muscle) may not have been ideal.

What happens to all these circulating "tumor cells"? The authors never identified or recognized any cells being phagocytized or undergoing degenerative changes. They believe these must be cancer cells, but the final proof is lacking.

"Insulitis" in Early Juvenile Diabetes. P. M. LeCompte. A. M. A. Arch. Path. 66:450-457 (Oct.) 1958 [Chicago].

The author reports on 2 infants, a boy and a girl, aged 11 months, a 9½-year-old boy, and a 17-year-old boy with diabetes mellitus who died within a short time after onset. Autopsy was performed on the 4 patients, and cellular infiltration, usually lymphocytic, of the islands of Langerhans was observed on microscopic examination of the pancreas in all of them. Some of the features of this rare but possibly significant lesion, described previously by other workers, were observed again, such as the variable appearance of the islands (of 2 islands of Langerhans in one patient, one appeared to be essentially normal, while the other showed lymphocytic infiltration); the narrow ribbon-like cords of cells with scanty cytoplasm and darkly stained nuclei, which are apparently alpha-cells and which probably are a manifestation of injury rather than of effective regeneration; the often peripheral distribution of the lymphocytes; and the occasional early fibrosis of an island. Hydropic change, the classical lesion of acute diabetes of recent onset, was seen in only 1 of the 4 patients but was also uncommon in the previously reported cases of "insulitis."

Cellular infiltration, usually lymphocytic, of the islands of Langerhans is observed most often in diabetes mellitus of acute onset and short duration in children. Its apparent rarity may be due in part to the fact that such acute cases come to autopsy only under exceptional circumstances. This "insulitis" may in a few instances be a response to actual invasion of the islands by an infectious agent, although this has not been demonstrated. It is more likely the aftermath of an injury which may differ from the injuries involved in the commonly recognized forms of experimental diabetes. It is probable that this injury in some way inhibits the regeneration of beta-cells.

Histochemical Proof of Organic Phosphate Poisoning. C. S. Petty, A. M. A. Arch. Path. 66:458-463 (Oct.) 1958 [Chicago].

The author reports a case of fatal organic phosphate poisoning in a 23-year-old man who on the morning of illness and death had been cleaning an airplane which had been used 5 days previously for crop dusting with Systox, an insecticide concentrate containing 26.2% of O,O-diethyl-O-2-ethyl mercaptoethyl thiophosphate (Demeton), 2.3% related organic phosphates, and petroleum distillate. Since all organic phosphates combine more or less irreversibly with the cholinesterases of the body, the red blood cell cholinesterase activity was studied during the acute phase of the illness and on autopsy, and the enzyme activity at the myoneurol junction in skeletal muscle was studied on autopsy. The abnormally low antemortem red blood cell cholinesterase level indicated poisoning by one of the organic phosphates. The low postmortem red blood cell cholinesterase level, together with the results of the histochemical staining of the intercostal muscle which did not provide evidence of cholinesterase activity, gave proof of fatal poisoning due to exposure to toxic organic phosphates. In vitro studies with human muscle and both in vitro and in vivo studies with rat muscle showed that Systox is capable of depressing the cholinesterase level at motor end-plates.

Whipple's Disease—Observation on Systemic Involvement: I. Cytologic Observations. J. C. Sieracki. A. M. A. Arch. Path. 66:464-467 (Oct.) 1958 [Chicago].

The author carried out cytological studies on autopsy specimens, including small intestine, mesenteric, axillary, inguinal, and peripheral lymph nodes, and various other tissues and organs, obtained from 7 patients who died of intestinal lipodystrophy (Whipple's disease). A widespread involvement of the tissues of all these patients was observed with cells which contained characteristic sickle-form, periodic acid-Schiff (P. A. S.)-positive cytoplasmic particles. These particles were found in mesothelial cells of the pleural, peritoneal, pericardial, and synovial lining cells. Their presence in a cell block of peritoneal fluid suggested the possibility of entertaining the diagnosis of Whipple's disease from such material. Smears stained according to Papanicolau technique left the characteristic particles unstained and showed the positive P. A. S. reaction when subsequently stained appropriately. Furthermore, the positive particles were diastase-resistant. In smears and imprints stained by the Romanovsky method, numerous vacuolated histiocytes were found. The nuclei of all histiocytes were similar in appearance. One group of these macrophages were the usual type of lipid-containing histiocyte "foam cells," with predominantly uniform-sized cytoplasmic vacuoles; another type, in which the apparent "vacuoles" were less distinct, varied in size and gave the cytoplasm a "moth-eaten" appearance. When these cytological preparations were subjected to the periodic acid-Schiff technique, these 2 varieties of histiocytes were again apparent. The histiocytes without lipid generally contained varying numbers of the sickle-form, positive-reacting particles. Less frequently, cells with uniform-sized vacuoles (foam cells) showed one or more positive sickle-form particles. This was particularly prominent in those preparations containing giant cells. The presence in the peripheral lymph nodes of cells with the characteristic cytoplasmic particle allows the diagnosis of Whipple's disease to be made during life without recourse to laparotomy.

Cerebral Mucormycosis: Report of a Case. M. E. Smith, D. K. Burnham and M. B. Black. A. M. A. Arch. Path. 66:468-473 (Oct.) 1958 [Chicago].

The authors report on a 38-year-old man with diabetes mellitus of 14 years' duration, who was admitted to hospital in coma. History showed that one week before admission he had sinusitis, with stuffiness in the nose and fever. At no time in his life had he had diabetic coma, and, although he was deeply comatose on admission, he did not have acidosis. There were marked proptosis of the right eye and edema of the right lid. He had difficulty in urinating. A clinical diagnosis of labile diabetes, subacute glomerulonephritis, and cavernous sinus thrombosis was made, and the patient received antibiotic therapy, intravenous fluids, and artificial respiration. He died 36 hours after admission.

Gross findings on autopsy consisted of hypertrophy of the heart, moderate coronary artery sclerosis, and edematous brain, with almost the entire right temporal lobe being replaced by clotted blood; a second hemorrhagic zone was near the midline of the cerebellar medulla on the right, extending into the upper pons. Both internal carotid arteries and the superior sagittal and right lateral venous sinuses contained thrombi. The cavernous sinuses also contained thrombus material. Microscopic examination revealed that both carotid arteries contained unorganized thrombus attached to the intima and tangled masses of broad branching nonseptate hyphae; the cavernous sinus contained small masses of thrombus and fungal hyphae, both free and invading nerves and fibrous fasciculi in the lumen. The walls of the cavernous sinus showed acute inflammatory reaction and hyphae. Hyphae were also observed in the submucosa of the sphenoid air sinus. An acute meningitis was confined to the area of the optic chiasm. A few hyphae lay inertly in the midbrain parenchyma above the chiasm, unassociated with inflammation. One bronchus was the site of an acute necrotizing ulcerating inflammation containing numerous hyphae. Other findings included advanced diabetic glomerulosclerosis, marked renal arteriosclerosis, bilateral chronic pyelonephritis, and multiple thromboses of small pulmonary arteries.

The true nature of the patient's disease was not discovered until the microscopic examination. Cultures for fungi were not made during life or at autopsy. The ethmoid sinuses and orbits were not investigated at autopsy. The evidence indicated that the infection arose in nose and paranasal sinuses and/or orbit and spread to the brain by way of the internal carotid arteries and cavernous sinuses. Proptosis and ophthalmoplegia were characteristic and apparently attributable to direct fungal invasion of the eye and retrobulbar space. In most cases collected from the literature, the mycotic infection was limited to the head. It is likely that in this patient the bronchial involvement was a separate primary focus, since there was clinical evidence of preceding orbital and sinus involvement. Characteristically there was total lack of inflammatory reaction to hyphae in some areas and a marked response in others.

Cerebral mucormycosis is a rare but distinctive entity, usually a rapidly fatal complication of diabetes mellitus. The case of this patient is a classical example. Since the 17 patients in the previously reported cases had rather stereotyped manifestations, more widespread knowledge of this condition should result in more frequent diagnoses during life and more thorough investigation at autopsy. Routine examination of paranasal sinuses in patients with diabetes mellitus coming to autopsy might help elucidate the pathogenesis.

Behavior of Leukocyte Sedimentation Rate in Tuberculous Disease and in Septic Infections. E. Lusvarghi, L. Bellesia and P. Mucci. Minerva med. 49:2735-2737 (July 11) 1958 (In Italian) [Turin, Italy].

Leukocyte sedimentation rates, according to the technique of Storti, were investigated simultaneously in 2 groups of patients. One group consisted of 20 patients with various types of pulmonary tuberculosis. The other group consisted of 10 patients with acute and chronic types of bacterial sepsis. Erythrocyte sedimentation rates were recorded for control purposes. Leukocyte sedimentation rates were determined before and several times during the treatment until the clinical cure of the disease. In patients with pulmonary tuberculosis and with bacterial sepsis the latter rates were above normal values. There was a close correlation between the leukocyte sedimentation rates and the Katz formula levels at the onset or at the termination of the disease. The leukocyte sedimentation rates were elevated and the Katz formula levels were within limits only in 1 patient with active bilateral tuberculosis of the apex and in 3 patients with bacterial sepsis. An increased level of fibrinogen seemed to be responsible for an elevated leukocyte sedimentation rate, whereas qualitative and quantitative changes in albumin and globulin values apparently had no bearing on it. Increased leukocyte sedimentation rates in patients with pulmonary tuberculosis and with bacterial sepsis indicated a probable direct participation of the leukocytes in the defense of the organism. Study of the leukocyte sedimentation rate is a useful diagnostic aid to be used along with the erythrocyte sedimentation rate. It can clarify in differential diagnosis certain roentgenologic findings in the lung and distinguish pulmonary tuberculosis from malignant tumors.

BOOK REVIEWS

Chronic Bronchitis, Emphysema and Cor Pulmonale. By C. H. Stuart-Harris, M.D., F.R.C.P., Sir George Franklin Professor of Medicine of University of Sheffield, Sheffield, and T. Hanley, M.D., M.R.C.P., Lecturer in Medicine of University of Sheffield. Written in collaboration with Marjorie Clifton, M.D., Research Assistant to M.R.C. Group for Epidemiological Research on Respiratory Diseases, London, Margaret M. Platts, M.D., B.Sc., M.R.C.P., J. D. S. Hammond, M.B., Ch.B., M.R.C.P., and W. Whitaker, M.D., M.R.C.P. Cloth. $8.50. Pp. 245, with 61 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44, Triangle West, Bristol 8, England, 1957.

The authors are to be commended on their choice of subject. Chronic bronchitis and emphysema are ubiquitous and imply serious consequences which more than justify bringing recent data to the attention of the medical profession. Each chapter carries worthwhile material. The authors recognize the smallness of the number of patients observed, which may detract somewhat from the weight of evidence presented. Even so, their focus on the salient features of these diseases, objectivity in observation, and sound logic in interpretation render the text of great value. The sincere dedication and praiseworthy thoroughness of the authors is impressive. Their preferential definition of chronic bronchitis is serviceable although it may not coincide with the concepts of other experts in this field. The clinical findings of chronic bronchitis are portrayed in an excellent manner. Various objective signs and findings on physical and x-ray examination are presented briefly but competently. The fallibility of some of the physical findings is well emphasized. The relation of infection to chronic bronchitis and emphysema is discussed concisely but adequately. Pathological and clinical aspects of emphysema are well described, although it is difficult to condone the omission of one of the cardinal pathological substrates of this disease, namely, destructive changes in the elastic elements of the lung.

There is a fine, practical section on pulmonary function studies. Nearly 60 pages deal with chronic cor pulmonale. Its incidence, clinical characteristics, and pathological physiology are skillfully covered. Current knowledge of pulmonary arterial blood pressure, cardiac output, oxygen-carrying capacity of the blood, and other related facets of the subject are assayed in lucid, easily readable fashion. The chapter on treatment is logical and methodical. Emphasis on the use of bronchospasmolytic drugs deserves special credit. Also commendable is the authors' cautious attitude toward the administration of narcotics as cough sedatives, and to use of oxygen for the relief of dyspnea. At the same time, their dogmatic negativism is hardly justifiable concerning artificial pneumoperitoneum and the surgical treatment of emphysema. The chapter on the epidemiology and pathogenesis of chronic bronchitis is written with critical analysis and is solidly documented. It contains tables and graphs that facilitate clear comprehension of the subject matter. The roentgenograms and photographs of gross specimens and histological preparations are of high quality. The case reports are of great didactic value. The references at the end of each chapter are well selected and up to date, and the index covers all essential items. Blank pages at the end of the book invite pertinent notes. This volume is likely to become a favorite with all those interested in diseases of the chest.

Bacterial and Mycotic Infections of Man. Edited by René J. Dubos, Ph.D. Aided by grant from National Foundation. Third edition. Cloth. $8.50. Pp. 820, with 116 illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1958.

This edition of a classic textbook combines bacteriology with practical clinical application. While the essential format of the previous editions remain the same, the book has been completely rewritten to present changing concepts concerning microbial diseases. A previous criticism of the book, that it lacked continuity, has been vitiated by its reorganization. New chapters include "The Evolution and Ecology of Microbial Diseases" and "Chemotherapy of Microbial Diseases." The first of the new chapters contains many points of view not necessarily shared by other contributors to the text, but these speculative concepts of infection versus disease (why do pathogens so often fail to cause disease after they have become established in the tissues?) provide a broad background to the understanding of disease determinants. Much praise must be given for the valuable material on antigen-antibiotic reactions and anaphylaxis. The chapter on the principles of sterilization should be valuable to every physician and his office staff.

While the general emphasis is on prevention and the potential disease state (host-parasite relationship), there is much information on the principles of chemotherapy as applied to clinical practice, including complete discussions on the individual

It contains tables and graphs that facilitate clear comprehension of the subject matter. The roentgenograms and photographs of gross specimens and histological preparations are of high quality. The case reports are of great didactic value. The references at the end of each chapter are well selected and up to date, and the index covers all essential items. Blank pages at the end of the book invite pertinent notes. This volume is likely to become a favorite with all those interested in diseases of the chest.

Bacterial and Mycotic Infections of Man. Edited by René J. Dubos, Ph.D. Aided by grant from National Foundation. Third edition. Cloth. $8.50. Pp. 820, with 116 illustrations. J. B. Lippincott Company, E. Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1958.

This edition of a classic textbook combines bacteriology with practical clinical application. While the essential format of the previous editions remain the same, the book has been completely rewritten to present changing concepts concerning microbial diseases. A previous criticism of the book, that it lacked continuity, has been vitiated by its reorganization. New chapters include "The Evolution and Ecology of Microbial Diseases" and "Chemotherapy of Microbial Diseases." The first of the new chapters contains many points of view not necessarily shared by other contributors to the text, but these speculative concepts of infection versus disease (why do pathogens so often fail to cause disease after they have become established in the tissues?) provide a broad background to the understanding of disease determinants. Much praise must be given for the valuable material on antigen-antibiotic reactions and anaphylaxis. The chapter on the principles of sterilization should be valuable to every physician and his office staff.

While the general emphasis is on prevention and the potential disease state (host-parasite relationship), there is much information on the principles of chemotherapy as applied to clinical practice, including complete discussions on the individual

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

chemotherapeutic agents. Other chapters contain discussions on human blood groups, epidemiology, principles and practice of diagnostic medical bacteriology, and specific pathogenic groups of bacteria and fungi. Because of financial support from the National Foundation, the book sells for a remarkably low price, especially considering the style of presentation (profuse tables, diagrams, and illustrations; excellent type and paper; complete index; and a careful, comprehensive bibliography) along with its content and its authors of exceptional reliability. The book is highly recommended to students and clinicians who deal with infectious disease.

A History of the Department of Internal Medicine, State University of Iowa College of Medicine, 1870-1958. By Walter L. Bierring, M.D. With introduction by William B. Bean, M.D. Cloth. $3.50. Pp. 116, with illustrations. State University of Iowa, Iowa City, 1958.

This little volume is of special interest because it has been prepared by Dr. Walter L. Bierring, whose life span began almost on the birthday of the College of Medicine of the State University of Iowa. It contains an interesting introductory chapter outlining the history of the College of Medicine and a brief one on the history of the department of internal medicine. The main body of the volume, however, is devoted to biographical and autobiographical résumés of the eight persons who have occupied the chair of the department originally called theory and practice of medicine, which today is the department of internal medicine. These brief sketches offer an interesting portrayal of the progress of medicine during this 90-year period. Those concerned with the management and utilization of the modern teaching hospital should find the description of the Rules and Regulations for the Government of the University Hospital in 1898-1899 of particular interest.

Cerebral Vascular Disease: Transactions of the Second Conference Held Under the Auspices of the American Heart Association, Princeton, New Jersey; January 16-18, 1957. Irving S. Wright, chairman. Clark H. Millikan, editor. Including classification and outline of cerebrovascular diseases. Report by ad hoc Committee established by Advisory Council for National Institute of Neurological Diseases and Blindness, Public Health Service. Cloth. $4. Pp. 224. Published for American Heart Association by Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

This book covers the problems of nomenclature and has, as an appendix, a classification and outline of cerebrovascular diseases prepared by a committee under the chairmanship of Dr. Millikan which should go a long way toward crystallizing thinking in this important area. The rest of the monograph deals with specific aspects of the subject presented by authorities in the field, together with the discussion which followed each presentation. Thus, Drs. R. D. Adams and H. Fang covered the anatomy and pathology of the cerebral blood vessels; Dr. G. Nylin discussed cerebral blood flow and blood pool; Dr. A. C. Corcoran, the interrelation of hypertension and cerebral vascular disease; Dr. J. P. Whisnant, experimental cerebral vascular disorders; Dr. C. M. Fisher, intermittent cerebral ischemia; Dr. J. Stamler, the cause and therapy of atherosclerosis; Dr. E. McDevitt, anticoagulant therapy; Dr. E. Cliffton, experiments on enzymes in treating thrombosis and embolism; Dr. E. H. Botterell, surgery of intracranial aneurysmal hemorrhage; and Dr. P. Lee, rehabilitation. The gaps in our knowledge are stressed. No one interested in cardiovascular diseases can afford to neglect reading this monograph carefully. It should go a long way in bringing to the fore a much neglected aspect of medicine. Dr. I. Wright, who was responsible for this symposium, as well as the first one deserves much praise, as do the persons and agencies who supported it. They and the participants have rendered a great service to the medical profession.

Clinical Endocrinology. By Karl E. Paschkis, M.D., Associate Professor of Medicine, Jefferson Medical College, Philadelphia, Abraham E. Rakoff, M.D., Clinical Professor of Obstetrics and Gynecologic Endocrinology, Jefferson Medical College, and Abraham Cantarow, M.D., Professor of Biochemistry, Jefferson Medical College. Second edition. Cloth. $18. Pp. 941, with 274 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1958.

This book is divided into sections on the anterior pituitary, posterior pituitary, thyroid, adrenal cortex, adrenal medulla, ovaries, placenta, testes, pancreas, parathyroids, obesity, and methods and materials. The chapters in each section deal with the embryology, anatomy, physiology, and disorders of the various glands. This book reflects the increase in endocrine knowledge since its first edition, particularly in the fields of thyroid and adrenal physiology, pathology, and therapy. The authors have done an extensive and commendable job of revising and, in some instances, rewriting chapters. They discuss in common-sense terms the male climacteric, the existence of which is denied by some authors. The term may be unfortunate, but few experienced observers will deny that some aging men exhibit the clinical findings mentioned by these authors. Their condition is greatly alleviated by the administration of androgens.

This excellent reference book suffers from the faults or weaknesses of all books in this field. There is an overemphasis on the value of laboratory findings and too little value attached to a careful history and physical examination. It also deals primarily with severe, far-advanced, "typical" cases. It is doubtful if this could be otherwise since the diagnosis is doubtful enough, in some instances, even in such cases, but disorders do have a beginning, a mild stage, before they become typical. These are seen not by endocrinologists, as a rule, but by general practitioners, surgeons, and internists. Such patients seldom have the time, means, or inclination to go through with a lot of expensive tests which at best may not be conclusive. Hyperfunction of the pituitary's eosinophilic cells is discussed as acromegaly. Gigantism is merely mentioned and yet in many cases it is preventable. In 1948 in a postgraduate course in endocrinology, irradiation of the pituitary was described as a method of preventing it. This mode had been used for 15 or 20 years at that time, in over 300 patients. The procedure has been in use for at least 25 years. Its discussion here would have been helpful. The authors would have done a great service to the American public and to the medical profession if they had included a chapter pointing out some of the signs and symptoms of endocrine disorders that could be elicited by a careful history and physical examination. Too often private practitioners are, by circumstances beyond their control, compelled to rely on the history and physical examination plus a therapeutic test. The more help we can give such men—and that means most physicians—the greater service we render the public and the profession. Incidentally, after the most extensive battery of laboratory tests the diagnosis can, in some cases, be settled only by a therapeutic test. This book should nonetheless be a valuable addition to any physician's library.

Congenital Anomalies of the Hand and Their Surgical Treatment. By Arthur Joseph Barsky, M.D., D.D.S., Professor of Clinical Surgery, Albert Einstein College of Medicine, New York City. Publication number 311, American Lecture Series, monograph in Bannerstone Division of American Lecture in Orthopaedic Surgery. Edited by Charles Weer Goff, M.D., Associate Clinical Professor of Orthopaedic Surgery, Yale University School of Medicine, New Haven, Conn. Cloth. $5.75. Pp. 165, with 77 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This excellent monograph is amply illustrated with roentgenograms and photographs of all deformities. Of particular value are the line drawings indicating the location of skin incisions in the operative repair of web fingers, floating thumb, lobster-claw hand, and other deformities. The work is based on a large personal series of 165 cases. It is well organized and has excellent chapters on incidence, cause, and various genetic, environmental, chemical, and endocrine factors. The effect of irradiation is briefly discussed, but, above all, the author has emphasized that heredity plays the greatest role in handing down defects to the germ plasm of the embryo. The bibliography is extensive and should be of great value. Credit is given to earlier authors for their pioneer work. The monograph is highly technical. It is a necessity in the library of the plastic surgeon and the orthopedist, but it is a little above the level of the medical student and the resident. To them it should be valuable as a reference book.

The Planning of International Meetings. Handbook issued by Council for International Organizations of Medical Sciences established under joint auspices of UNESCO and WHO. Paper. $2.50. Pp. 113. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada; published in French by Masson & Cie., 120 boulevard Saint-Germain, Paris 6e, France, 1957.

Those who have attempted to plan international meetings know the problems that can arise when men and women from various parts of the world attempt to meet on a common medical ground. While the spirit and the knowledge may have much in common, procedure can vary tremendously and is often an unnecessary source of irritation, particularly if improper planning is evident. This booklet is an attempt to provide guidance for planning and is worthy of careful study by those who are interested in the planning of such meetings, as well as by those who merely hope to attend but would like to get the most out of such sessions.

Manual of Medical Emergencies. By Stuart C. Cullen, M.D., Professor of Surgery; Chairman, Division of Anesthesiology, State University of Iowa College of Medicine, Iowa City, and E. G. Gross, M.D., Professor and Head of Department of Pharmacology, State University of Iowa College of Medicine. Third edition. Cloth. $5.75. Pp. 302, with 41 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1958.

This handy pocket-size book provides information without wasted details on many common problems that confront the practitioner. It is not as comprehensive as many textbooks are, but apparently it is not intended to be. Rather, it is to be used for quick reference. In this respect, interns and general practitioners may find it of greater value than others. There may be some forms of treatment, particularly with the newer drugs, that would be found missing, but this is the hazard associated with writing any medical book. Furthermore, there may be a dispute about treatment (such as the recommendation that a snakebite wound should be incised), but such criticisms do not detract from its usefulness.

The Early Diagnosis of the Acute Abdomen. By Sir Zachary Cope, B.A., M.D., M.S. Eleventh edition. Cloth. $4.50. Pp. 188, with illustrations. Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England; 114 Fifth Ave., New York 11; Amen House, 480 University Ave., Toronto 2, Canada, 1957.

This popular book has gone through sufficient editions to justify its broad acceptance. It is practical, helpful, and easily understood. Unfortunately, there is an appearance of crowding of type on the pages so that it is not easy to read, but for those who desire a ready reference source, to which they can go for a subject or a symptom without attempting to cover a system or the body as a whole, this book should be found practical because of the directness with which the author discusses the problem.

QUESTIONS AND ANSWERS

PREVENTING STAPHYLOCOCCUS INFECTIONS IN THE NURSERY

To the Editor:—*In an attempt to control contamination by staphylococci in a hospital nursery, is there any practical value in obtaining nose and throat cultures on newborn infants at the time of discharge on the third day?*

M.D., South Carolina.

Answer.—Nose and throat cultures taken at the time of the baby's discharge from the hospital on the third day give important evidence in preventing an epidemic in the nursery by detecting carriers. They are also important in controlling an epidemic already present by giving information which would aid in tracing the method of spread of staphylococci in the nursery. This information supplements more important data from nose and throat cultures on asymptomatic mothers, nurses, and other personnel and from cultures from skin, blood, stools, and urine of infants and mothers with clinical evidence of infection. The greatest value of routine nose and throat cultures at the time of discharge would be to the family physician or pediatrician who attends the infant in the home. Such information would enable the physician to administer the appropriate antibiotic to infants with positive cultures before the onset of symptoms. It is important, therefore, that culture reports be immediately available to the family physician or pediatrician, as well as to the house staff.

PTYALISM

To the Editor:—*A 30-year-old man has been suffering from hypersalivation (ptyalism) for about 15 years. No dietary or emotional basis can be found for this annoying condition which fills up his stomach with saliva, causing heaviness in the upper abdomen and nausea. No pathology can be found locally. Anticholinergic drugs, atropine, and local mouth irrigations do not give any degree of improvement. Please advise what can be done for relief.* *M.D., New York.*

Answer.—The hypersalivation would not cause "heaviness in the upper abdomen and nausea." The hourly secretion of "resting" salivary glands equals 15 cc., and the total amount of saliva secreted daily varies from about 600 to about 1,500 cc. or more. It is unlikely that even a substantial amount of hypersalivation would be related to the nausea in this case. On the contrary, nausea itself is a powerful stimulus for the salivary glands and would, therefore, cause hypersalivation. Therefore, a search for the actual cause of the nausea is in order. For example, one should be certain not only that the gastrointestinal series shows normal findings but that a barium enema and gallbladder studies also show normal results. If no organic basis for the nausea can be found, simple abdominal distention with gas may be the explanation and can be treated by the administration of belladonna tincture, 0.6 cc. before meals and at bedtime, and pavatrine, 125 mg. after meals; by the avoidance of iced drinks and cold foods; and by the taking of a hot drink before each meal. The following diet may be of value:

One-half glass of orange juice, diluted with one-half glass of hot water, should be taken on arising. If stools are hard or infrequent, this same amount of orange juice and hot water should be taken before each meal. If stools are loose, the orange juice should be omitted until they are formed. For breakfast, the following foods may be chosen from: Any cooked fruit, fresh, dried, or canned, may be stewed or baked. If canned fruit is used, it should be brought to a boil and cooled before eating. Well-cooked oatmeal or cream of wheat may be used, with puffed wheat and puffed rice during the summer. Bacon should be broiled and eggs soft-boiled, poached, baked soft in a ramekin dish, or scrambled in the top of a double boiler. Toast, preferably melba toast, should be of white bread, with butter spread on as it is eaten. Tea, coffee, or milk may be used (not more than one cup of coffee daily). The noon and evening meals may be chosen from the following list of foods: raw oysters, broth, or creamed soups made from the vegetables which are allowed on the diet; any white fish, such as halibut or haddock, or hot boiled lobster (no mackerel, salmon, clams, or any oily fish; fish should be boiled, broiled, or baked); beef, lamb, chicken, or broiled liver or kidneys; turkey, duck, and partridge (no dressings or gravies; meats may be in any form except boiled or from the frying pan or deep fat); potato, rice, or macaroni once or twice daily; native (garden) lettuce and celery—if possible, twice a day; other vegetables as follows: string beans, asparagus, spinach, carrots, raw carrot sticks, peas, cauliflower, beets, squash, artichokes, eggplant (boiled or broiled, not fried or scalloped),

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

and mushrooms, not sautéed; and desserts as follows: jello, cooked fruit, soft puddings, American, cream, cottage, Gruyère, Port du Salut, or Swiss cheese, and sponge or angel cake. White bread, or very fine graham bread, should be used, preferably cut thin and toasted dry, with butter to be spread on as it is eaten.

REGIONAL ENTERITIS AND ABSORPTION

To the Editor:—*A woman, aged 32, developed ankle edema with some constant and persistent pain in the lower part of the abdomen after delivery of her last child. The abdomen is slightly distended. There are no palpable masses and no tenderness on palpation. Examination of the intestines showed the lower portion of the ileum to be thickened for about 24 in. The diagnosis was regional ileitis. At operation, about 3 ft. of ileum was removed, with some enlarged mesenteric glands. She received about 5 units of serum albumin (low salt) and was advised to be on a high-protein diet. From 1945 until 1956 she had repeated blood protein examinations at about six-month intervals. The serum albumin level has always been low, and 6-10 intravenous injections of serum albumin, 25 mg. units, have been given. She has had persistent diarrhea since the operation. Repeated x-rays of the intestines at about yearly intervals revealed some recurrence of the ileitis. In 1956, she developed ascites, for which repeated taps were done, with recurrence every six days. In June, 1957, she was given 10 units of serum albumin intravenously; all liver function tests gave normal findings, and hematology was the same as in 1945. Exploratory examination of the abdomen revealed some extension of the ileitis. Liver, adnexa, stomach, large intestines, and the rest of the abdominal viscera were normal, and no reason for the recurrent ascites could be found. After six weeks of hospitalization she was discharged with instructions to be on a low-sodium and high-protein diet. Since July, 1957, she has received about 30 units of a serum albumin. She has lost about 20 lb. (9.1 kg.) in weight. She is taking chlorothiazide, 500 mg. three times a day, and is on a sodium-free diet, but the ascites is worse than ever, her appetite is very poor, and diarrhea persists. Urine output is normal. The blood protein level is always low before the serum albumin administration and returns to normal after. At present, she is very weak and hardly able to move about (weight, 102 lb. [46.3 kg.]). Please discuss etiology and treatment.* *David Cohen, M.D., Philadelphia.*

Answer.—The description in this case is that of a rather extensive, advanced regional enteritis, with possibly more involvement than is visible to the naked eye. In some of these patients there is great interference with the processes of absorption. A deficiency state occurs, resembling that resulting from long-standing depletion of protein or withholding of protein. The etiology of regional enteritis is, of course, obscure. The symptom complex described in this patient's case resembles that occasionally seen in a patient with regional enteritis in which the lesions are roentgenographically rather limited yet in which changes throughout much of the small intestine occur. Some of these patients have responded to roentgen therapy (Bargen, J. A. M. A. 165:2045-2047 [Dec. 21] 1957). A high protein intake should be maintained. Edema and ascites may well be associated with lack of protein absorption.

TERTIARY SYPHILIS AND YAWS

To the Editor:—*Is there a definite method of differentiating between tertiary syphilis and tertiary yaws (framboesia)? The modifications of the Wassermann test (Ide's, Kolmer's, and others) and the Treponema pallidum immobilization test both may give positive results in either disease. What is the present treatment of choice in yaws? Has broad-spectrum antibiotic therapy given lasting and irreversible results? In a patient allergic to penicillin, would erythromycin, 500 mg. given every four hours for 30 days, be regarded as satisfactory treatment for tertiary syphilis? What would be recommended as alternative therapy?* *David N. Shapiro, M.D.*
Johannesburg, South Africa.

Answer.—There is no way of differentiating serologically between lesions of tertiary syphilis and yaws. The Treponema pallidum immobilization test has so far revealed no essential immunogenic differences between the treponemes of syphilis and yaws (Grin, *Bull. World Health Organ.* 15:959, 1956). Some clinical differentiations between them are well outlined by Furtado (*A. M. A. Arch. Dermat.* 76:446, 1957). Penicillin is the treatment of choice in yaws. In Haiti, 258 patients with early yaws were "cured" with sterile procaine penicillin G with aluminum stearate suspension. Injections of 1 cc. at 12-hour intervals were given for four days for a total of 2,400,000 Oxford units. Rein stated, "There are no proven instances of either clinical re-infection or relapse in the patients followed for one year" (*Ann. New York Acad. Sc.* 55:1179, 1952).

Benzathine penicillin G, the delayed and long-acting penicillin, may give similar results with 1,400,000 units. Smith and co-workers (*Bull. World Health Organ.* 15:1087, 1956), in a follow-up report after two years of treatment of early syphilis, found that one injection of 2,400,000 units of benzathine penicillin G produced a higher clinical and serologic cure than 4,800,000 units of procaine penicillin G with aluminum stearate suspension given in two to four sessions. Benzathine penicillin G also gave "satisfactory" clinical and serologic results in the late cases of yaws observed by Furtado. The results of treatment of yaws with broad-spectrum antibiotics are inconclusive, but apparently these are not as effective as penicillin.

Ampofo and Findlay (*Tr. Roy. Soc. Trop. Med. & Hyg.* 44:311, 1950) treated six children with secondary yaws with orally given oxytetracycline. They received either three or four capsules twice daily for seven days, for a total of 10.5 to 14 Gm. Dark-field examinations became negative within 24 to 36 hours, and healing of the lesions was complete in one to four days. Three months after the completion of therapy, all had shown a reduction in titer on serologic testing but none attained seronegativity. Oxytetracycline apparently exerts only a bacteriostatic effect, in contrast to the bacteriocidal effect established for penicillin.

Erythromycin, although not used extensively, appears to be as effective in syphilis and yaws as the other antibiotics, such as chlortetracycline and oxytetracycline. Furtado mentions erythromycin as one of the antibiotics which have been proved effective clinically and serologically in the treatment of yaws. Thomas (*J. A. M. A.* 162:1536-1539 [Dec. 22] 1956) and Olansky and Garson (*A. M. A. Arch. Dermat.* 77:476, 1958) found that the broad-spectrum antibiotics given in 1-Gm. doses every six hours for seven days were as effective as penicillin for treatment of early syphilis. In latent and late syphilis, similar doses are given for 15 days and in neurosyphilis for 30 days. Half of that amount may be given in twice the number of days if the patient can not tolerate 4 Gm. of the antibiotic a day. Oxytetracycline is better tolerated than chlortetracycline. From these reports, it is evident that 90 Gm. of erythromycin should be considered adequate treatment unless the patient has neurosyphilis, when 120 Gm. would be required. In latent and late syphilis, neurosyphilis, and late lesions of yaws, only symptomatic and clinical results may be expected with adequate therapy, as mentioned, with no reversal in serologic fastness.

MUSCLE CRAMPS

To the Editor:—*What is the cause and treatment of muscle cramps? Is there any relationship between them and the use of calcium in the form of phosphorus or carbonate?*

M. G. Radewan, M.D., Wenatchee, Wash.

Answer.—Practically anything that interferes with the nutrition and gas-exchange of normally innervated skeletal muscle can cause the painful contractions called cramps. This is illustrated by the fact that cramps are seen in both sodium intoxication and sodium depletion and in both oxygen intoxication (as when divers inhale oxygen under pressure) and intermittent claudication (ischemic pain in peripheral vascular disease). It is generally assumed that the calcium ion has a relaxing effect on skeletal muscle, yet it antagonizes the magnesium ion which likewise has a relaxing effect. The calcium ion antagonizes both the inhibitory effects of potassium and the stimulant effects of sodium. The concentration of calcium in the blood is greatly reduced by intravenous injections of phosphoric acid or sodium phosphate, yet rather large doses of these two substances are necessary in order to induce tetany. These conflicting facts of experiment do not afford a secure basis for preferring phosphate-free compounds of calcium in the treatment of muscle cramps. There are some products on the market which have been promoted for preventing muscular spasms in pregnancy and which contain the calcium in the form of carbonate or lactate. But it remains to be proved that these phosphate-free compounds, as sources of calcium, are better than calcium phosphate. In elderly patients the most common cause of muscular cramps at night is impaired circulation through the muscles, and the logical treatment is active and passive exercise with or without the use of such vasodilator drugs as ethyl alcohol, theobromine sodium acetate, and nylidrin hydrochloride.

REMOVAL OF IMBEDDED TICKS

To the Editor:—*Please advise on suitable methods to prevent dog ticks from becoming attached to the skin while a person is in brush and weeds. Once the pests are imbedded, how should they be removed without leaving the parasite's body in the skin? Is there any effective antipruritic?*

Harold R. Peasley, M.D., Des Moines, Iowa.

Answer.—The best way to prevent tick bites is to avoid heavily infested areas during the spring and summer months. If one must venture into these areas, protective clothing with elastic at the openings and high boots should be worn. The openings of the clothing or the entire garment may be sprayed with tick repellents. One of the best repellents is *N*, *N*-diethyltoluamide, which may be obtained in a concentration of 50% in a liquid or 15% in a spray. The U. S. Army has had considerable success with M-1960, which consists of equal parts of *n*-butylactanilide, 2-butyl-2-ethyl-1,3-propanediol, and benzyl benzoate, with 10% polysorbate 80 as emulsifier (Chandler, Parasitology, ed. 9, New York, John Wiley & Sons, 1955, p. 519). While 10% DDT powder is not effective against all species of ticks, it may afford some protection. The body and clothing should be inspected twice a day, if possible, for ticks. Ticks may be removed by touching them with the end of a lighted cigarette, by coating the tick with fingernail polish or petrolatum, or by grasping the tick with a pair of forceps and twisting the head and mouth parts free. Care should be taken not to crush the tick lest the infectious contents be spilled into the wound. Paint the bite with an antiseptic—iodine tincture is a good one. Antihistamine ointments may produce some antipruritic effects when applied to the bites.

DESENSITIZATION OF RH-NEGATIVE MOTHER

To the Editor:—*About one year ago there was an article concerning a haptene that was being experimentally used to desensitize the Rh-negative mother during pregnancy and the newborn infant. Has this substance been developed further? Is it commercially available, and if so, from whom? Are there any recommended prophylactic measures other than hesperidine and ascorbic acid?*

A. D. Heetderks, M.D., Bozeman, Mont.

Answer.—Many years ago it was shown that the so-called Rh haptene had no specific activity in in vitro tests and that the injection of this material had no effect on the degree of sensitivity of the mother during the pregnancy or on the newborn infant. Hesperidine and ascorbic acid have also been found to be of no real value in such cases, although the use of vitamin C and other vitamins is generally recommended as part of the management of all expectant mothers. In fact, there is no known prophylactic measure of value for treating sensitized expectant Rh-negative mothers. The only treatment of established value is exchange transfusion on the baby, which, of course, can be applied only after the baby is born. For fuller details, the following reference may be consulted: Wiener, "An Rh-Hr Syllabus" (vol. 9, Modern Medical Monographs, New York, Grune & Stratton, Inc., 1954).

CATARACT SURGERY

To the Editor:—*What are the schools of thought pertaining to the indications for removal of a cataract which has not ripened to maturity? Also, would it be advisable to remove an unripened cataract from one eye, with the best corrected visual acuity of 20/200 or less, in a person who is blind in the opposite eye as a result of injury or any surgical procedure for an eye impairment?*

Joseph Bogan, M.D., Hyattsville, Md.

Answer.—In recent years the question of whether or not to operate on a patient with an immature cataract has become nearly academic. The maturity of the lens has no role in the decision concerning cataract surgery with intracapsular lens extraction for the improvement of vision. Nuclear sclerosis and posterior subcapsular cataract rarely progress to maturity, and most surgeons believe that it is not necessary to carry out artificial procedures either to make the remainder of the lens opaque or to delay surgery. The decision concerning the time of operation is usually related to how much the visual defect interferes with the patient's activities. A housewife may be moderately content with 20/200 vision, while a businessman or physician would find it impossible to carry on with this degree of visual reduction. Generally, blindness in the opposite eye is no indication for delaying surgery once the vision impairment interferes with the patient's activities.

COLORING OF SEMINAL FLUID

To the Editor:—*A healthy, 33-year-old married man has a complaint of flecks, which resemble graham cracker crumbs in color and consistency, in his seminal fluid. Physical examination revealed no abnormality of the urogenital tract. The result of a Papanicolaou smear of prostatic secretion was reported as negative. He had been taking two high-potency multivitamin capsules daily. He states that the discoloration ceased when he stopped taking the vitamin capsules. Is there any possible connection between the "flecks" in the seminal fluid and the large amount of multivitamin and mineral ingested?*

L. J. Steffan, M.D., Plymouth, Wis.

Answer.—A thorough search of the recent literature has failed to yield any information relative to the "graham cracker flecks" found in the semen. Normal semen is known to contain lecithin, cholesterol, and phosphorized fat. Whether an increase in these constituents after the ingestion of high-potency multivitamin capsules could produce such bodies cannot be answered. This consultant is aware of many unpublished reports of the coloring of semen by a variety of medicaments, but all of these await confirmation.

ALLERGY TO PENICILLINASE

To the Editor:—*Please furnish information regarding the toxic and allergic reactions induced by the use of penicillinase. What is its value in treating an immediate reaction to penicillin?*

M.D., California.

Answer.—This consultant has heard specifically of at least two reactions to penicillinase; these were in the nature primarily of fever and toxic effects resembling reactions to foreign protein rather than anaphylactic shock. Febrile reactions are also mentioned by Dr. M. C. Zimmerman in his published articles. The major consideration, of course, is that penicillinase is an enzyme, and therefore a protein, and that the likelihood of allergic reactions must be anticipated, possibly on the first administration but more likely after repeated administration in the same individual. Penicillinase does not work fast enough to be of appreciable value in the treatment of immediate reactions to penicillin. It may be of value in delayed reactions.

SEASONAL ALLERGIC RHINITIS

To the Editor:—*Is the incidence of complications increased, decreased, or the same after the treatment of uncomplicated seasonal allergic rhinitis (i. e., no asthma or polyps) with antihistamines alone, as compared to that with hyposensitization? Mothers are not anxious to commit themselves to a protracted schedule of regular visits, especially when the children are fearful of injections. Is there any harm in advising treatment with the antihistamine which gives satisfactory relief and waiting until the child is older and more able to cooperate and understand the reason for frequent injections?*

M.D., New Jersey.

Answer.—Evidence that the use of antihistamines in hay fever diminishes or increases the likelihood of such complications as asthma or polyposis is not conclusive. However, the incidence of asthma in persons sensitive to ragweed pollen is about 35% or 40%, and desensitization is effective in preventing the patient with simple hay fever from developing asthma. Thus, it is not the use of antihistamines but rather the omission of desensitization which is the important issue.

DIABETES AND RETINAL HEMORRHAGE

To the Editor:—*A diabetic patient, taking one tablet of tolbutamide daily, had a retinal hemorrhage. Is it possible that this was caused or precipitated by the drug?* *M.D., New York.*

Answer.—As far as is known, there is no evidence to date to indicate that the taking of tolbutamide would cause or precipitate a retinal hemorrhage. Unfortunately, such hemorrhages occur frequently in patients with diabetes, particularly after 10 or more years' duration of the disease. There is considerable evidence to suggest that retinitis occurs earlier and more severely in patients whose diabetic condition has not been well controlled. Some have raised the question as to whether, over many years of the presence of diabetes, sulfonylurea compounds will protect the patient against vascular complications as well as insulin does. However, the answer to this must await the passage of time.

RECURRENT NIGHT SWEATS

To the Editor:—*In the Oct. 11, 1958, issue of* The Journal, *page 843, is a request for advice concerning night sweats. In one treated patient, propantheline bromide was not effective but methantheline bromide, 100 mg., gave complete control. Before the drugs are used, tests must be done to rule out any infection.*

J. W. Robinson, M.D.
2686 Locksley Pl.
Los Angeles 39.

To the Editor:—*With reference to the Question and Answer on recurrent night sweats, which appeared in* The Journal, *Oct. 11, 1958, page 843, a relatively rare cause was not mentioned. Autopsies were performed on two patients with pheochromocytoma who had essentially identical histories. The symptom complex as described warrants investigation along this line. One patient, a 28-year-old primipara, complained of drenching night sweats to the extent that she would have to change her bedclothes several times each night. This began at the third month of pregnancy and persisted to the time of delivery, which was performed by cesarean section because of preeclampsia. Twelve hours later she went into shock and died. A pheochromocytoma of the left adrenal was found. The second patient was a 40-year-old man who had suffered intermittent severe headaches for 10 years. The diagnosis of pheochromocytoma was considered two years prior to his death. Tests with use of phentolamine at that time gave negative results. He, too, experienced night sweats in the year prior to his death. His death occurred during an acute episode associated with hypertension, marked perspiration, and a shock-like state. Again, autopsy revealed a pheochromocytoma of the left adrenal.*

J. Weinberg, M.D.
3230 W. Franklin Blvd.
Chicago 24.

ISOLATION OF PATIENTS WITH STAPHYLOCOCCUS INFECTION

To the Editor:—*In answer to the question on isolation of patients with staphylococcus infection, which appeared in* The Journal, *Oct. 4, 1958, page 716, the consultant states, "All patients should be masked while they are in the operating room." I believe this should read "All personnel should be masked while they are in the operating room."*

Bruce B. Rolf, M.D.
12300 Wilshire Blvd.
Los Angeles 25.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*This consultant meant that not only the personnel but all patients should be masked while in the operating room. It would be an error to limit it to the personnel, because occasionally a guest doctor, consultant, or medical relative are also privileged in being in the operating room. The statement that "all patients should be masked while they are in the operating room" should be accepted. This leaves no exceptions.*

WASHINGTON NEWS

FROM THE WASHINGTON OFFICE OF THE AMERICAN MEDICAL ASSOCIATION

Governors Informed of Plans for Conference on Aging . .

Cancer Chemotherapy Program in Full Sway . .

President Approves Forming Science Information Service . .

Emphasis on Science Damaging School Health Programs . .

ALL GOVERNORS INFORMED ABOUT CONFERENCE ON AGING

Secretary Flemming, Department of Health, Eduation, and Welfare, has written all governors, reminding them of the White House Conference on Aging, scheduled for January, 1961, and pointing ut to them that the U. S. is prepared to give states rom $5,000 to $15,000 to help in the project. The money may be used to help finance state and local onferences, which are to precede the Washington meeting, and for travel expense of delegates to the ational session.

HEW Under Secretary Bertha Adkins noted that housands of people, far more than could attend the White House sessions, will be able to take part in tate and local meetings. "There should be as wide participation as possible in these meetings," she aid, "including voluntary organizations, legislators, tate officials responsible for welfare activities, ndividuals, and of course, the aging themselves. "Suppose medical research results in adding several more years to life expectancy. This, we want o happen and are working hard to accomplish but we should not be unprepared for the socioeconomic roblems this would bring. Consider for a moment what might happen in Washington if the Public Health Service through research at the National nstitutes of Health should suddenly find a way to halt all heart disease. Such news would send a thrill f hope and relief around the world. It would also present new problems.

"Estimates of actuaries now would be out of the window. What would happen to the Old-Age and urvivors Insurance system if beneficiaries began drawing benefits for much longer periods than originally estimated? Would increased annuity payments cause private insurance companies to ounder?

"The moral of the story is that in the field of aging we are dealing with millions of people and billions of dollars."

CANCER CHEMOTHERAPY PROGRAM IN FULL SWAY

The board collaborative effort to discover chemical compounds that will be effective and safe in the treatment of cancer is in full-scale operation. Secretary Flemming of the Department of Health, Education, and Welfare describes it as a "massive effort by hospitals, universities, research laboratories, industry, and government."

The program is supported and centrally directed by the Public Health Service through the Cancer Chemotherapy National Service Center at the National Cancer Institute. Initiated by Congress in 1953, the program has been steadily expanded. Mr. Flemming listed the following facts to illustrate the scope and magnitude of the effort:

1. Over 40,000 chemical compounds or other materials are being tested annually on more than a million mice to uncover chemicals with anticancer properties. To date more than 70,000 materials have been put through this initial screening process.
2. Between 400 and 600 materials a year are showing sufficient promise in the initial screenings to be given further intensive analysis and testing, including tests in larger animals. In this phase, which takes about six months to complete, more than 9 out of 10 materials are rejected either as ineffective or too toxic for human use.
3. About 40 or so materials a year, or roughly one out of a thousand of all those originally entering the program, are being approved for clinical trials with human patients in some 150 cooperating hospitals in the U. S.

About 70 materials are now undergoing clinical trials, including some newly developed compounds and some that were already in use. The secretary said the Chemotherapy Service Center this year has let 73 contracts totaling $8,300,000 with universities, research laboratories, and nonindustrial institutions and 19 contracts of $4,500,000 with private industrial firms. They cover most of the testing work and a wide range of other projects, including the synthesis or production of complex new chemical compounds. In addition, 140 grants amounting to $3,800,000 have been made so far this year to support clinical trials with cancer patients. The center's budget for this fiscal year is 23 million dollars.

Mr. Flemming said, "It is important, of course, not to raise premature or false hopes for a drug cure for cancer. So far, none of the drugs being tested has proved to be a cure for cancer. The only existing cures for cancer are through treatment by radiation or surgery. The Surgeon General, however, advises me that some promising new compounds developed in the chemotherapy program are now being tested against a variety of cancers, especially acute leukemia and cancers of the breast and stomach."

(Continued on page 28)

'CARDILATE' sublingual tablets for angina pectoris

"Nitroglycerin and erythrol tetranitrate when administered sublingually are among the most effective of all prophylactic agents available for the treatment of patients with angina pectoris. The comparatively *prolonged duration of action of erythrol tetranitrate* makes it especially valuable for clinical use."

Riseman, J. E. F., *et al.*: Circulation *17*:22, 1958

'Cardilate' brand Erythrol Tetranitrate
Sublingual Tablets 15 mg., scored.

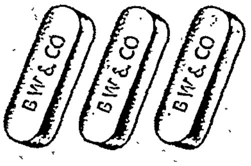
'CARDILATE'



SCIENCE INFORMATION SERVICE APPROVED BY PRESIDENT

A plan designed to help coordinate the grow volume of scientific information published here a abroad, and thus make more of it available to sci tists, has been approved by President Eisenhow

In a report of his Science Advisory Committ headed by James R. Killian Jr., Ph.D., the Natio Science Foundation was directed to expand scientific information program to constitute a s ence information service "that would serve to a and coordinate existing governmental and priva efforts." The White House announcement said t President's action strengthens and reinforces t provision of the National Defense Education A of 1958, which calls for a science information ser ice within the foundation.

The President's committee urged that fullest u be made of existing information services, both pu lic and private, and that the NSF service suppl ment rather than supplant present efforts.

Comments the committee: "The reason scienti information has become a major problem, pa ticularly since World War II, is that the rapid ra of scientific progress has multiplied the volume scientific information to a point where it can longer be published and handled within the fram work of existing methods. When one considers, to that much of what is significant in science is bein published in unfamiliar languages, it is clear th the working scientist is faced with almost insupe able problems in attempting to keep himself in formed on what he needs to know.

"Some idea of the volume of increase may b had from the fact that the science and technolog periodical collections of the Library of Congres have doubled approximately every 20 years for the past century and now contain approximately a mil lion and a half volumes, a significant fraction of the Library's total bound collections. The Library is receiving journals in science and technology at the rate of about 15,000 annually, and 1,200 to 1,500 new periodicals are appearing each year. Yet the library receives less than a third of the 50,000 scien tific periodicals that appear in the world list of 1952, and it is expected that by 1979 the total world output will reach 100,000 journals.

"The language difficulty is reflected in the fac that Russian-language publications are estimated t account for a tenth or more of all the scientific lit erature being published in the world today. Thi Russian total is second only to English."

EMPHASIS ON SCIENCE IS DAMAGING SCHOOL HEALTH PROGRAMS, CONFERENCE TOLD

Growing emphasis on teaching of science an mathematics threatens to wreck school health pro grams, in the opinion of a group of health an recreation leaders gathered in Washington.

The meeting was the Conference on the Physic Fitness of Secondary School Youth, called by th American Association of Health, Physical Educatio and Recreation (AAHPER). Cooperating were number of private and public groups, includin President Eisenhower's Council on Youth Fitnes

"If today's teenagers are to be the nation's space ship operators and rocketmen in the not too distan future, the high schools are going to have to them keep their 'fitness quotients' as high as thei IQ's," AAHPER cautioned.

The health and physical education section of the rence agreed that, since Sputnik, the emphasis been so strongly in the direction of mathe- tics, science, and engineering that the physical cation and health programs have been or will be seriously curtailed.

Paul E. Elicker, executive secretary of the Na- ional Association of Secondary School Principals, nade a strong appeal for improving schools by xtending the school day instead of reducing the resent curriculum to make room for more mathe- natics and science. He said there was a danger to ducation in the proposed four-day work week hat has some popular support. He is convinced that here would be a strong temptation for some par- nts to keep their children out of school the extra lays they are away from the job. The result, Mr. licker feels, would be to drastically shorten the ffective school week.

CUT-OFF DATES FOR DEFENSE EDUCATION FUNDS

Department of Health, Education, and Welfare as set cut-off dates for applications for funds under he National Defense Education Act passed by the ist Congress. The last postmarked date for applica- ons from colleges and universities in the fellow- ip program is Dec. 31, 1958. For the student loan rogram, the last date is Jan. 6, 1959. While no ormal application procedure is contemplated for ie counseling and guidance institutes, schools lanning to propose institutes for the summer of 959 are urged to submit their proposals prior to eb. 1, 1959.

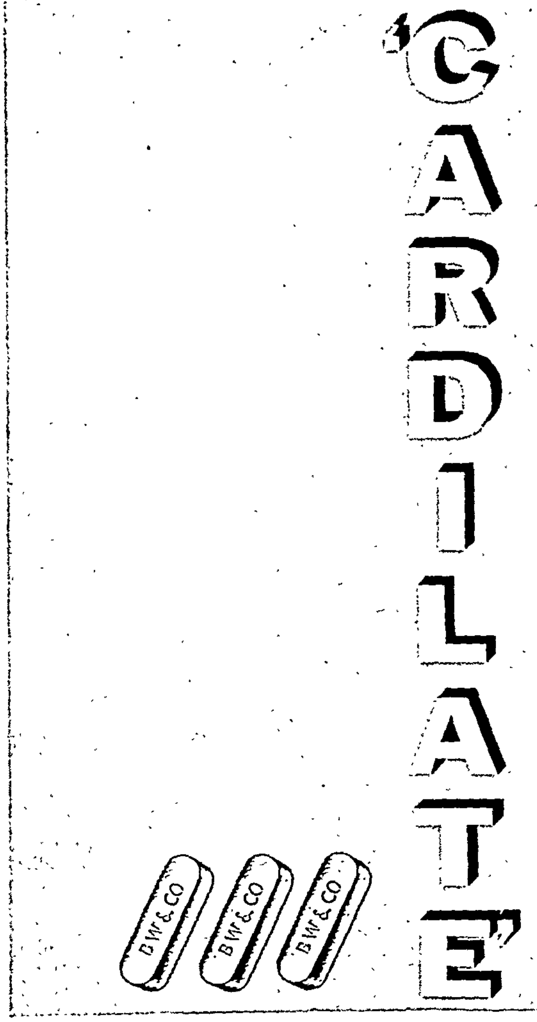
OCDM TO TAKE OVER FUNCTIONS OF COMMITTEE

On Jan. 1, the Office of Civil and Defense Mo- ilization will take over the functions of a presi- ential committee that for more than two years has een carrying on a campaign to identify bright udents and encourage them to study science and ngineering. The group is the President's Committee on Scientists and Engineers. While no physician is on the committee, its leaders have encouraged doctors at the local level to work with other professionals to encourage talented students to continue their educations.

Under OCDM, with E. L. Keenan in charge, the committee will continue with its program. Local action kits and questionnaires will be issued to any doctors or others interested in promoting the committee's efforts.

Doctors who have worked with the committee point out that unless medicine makes an organized effort to channel a fair share of capable students to medical colleges, the practice and teaching of medicine will suffer in the future, when a preponderance of the best students will be in other scientific and engineering careers.

Those familiar with the problem of improving the teaching of science and mathematics in secondary schools feel strongly that there cannot be good instruction in these subjects unless the whole school curriculum is strengthened. They caution that the curriculum should not be overweighted in the science field. Physicians who have been active in the committee's work have, among other things, attempted to insure that biology is not neglected as a major science.



'CARDILATE'
sublingual
tablets for
angina pectoris

Sublingual administration obviates inactivation of nitrites in gastrointestinal tract.

Most closely approximates nitroglycerin in frequency and degree of effectiveness.

'Cardilate' brand Erythrol Tetranitrate
Sublingual Tablets 15 mg., scored.

EDUCATION IN MOTOR VEHICLE ACCIDENT PREVENTION

Amos E. Neyhart, University Park, Pa.

I WOULD LIKE to start my discussion with an appropriate quotation from the yearbook "Safety Education" prepared in 1940 by the American Association of School Administrators: "It is to the school particularly that we must look for the development of the knowledge, the attitudes, the habits, and the skills that are necessary if we are to live with reasonable safety in the modern world."

This quotation, I think, is especially appropriate at this time when we are putting renewed emphasis on education as a result of the launching of satellites by Russia and the United States. It is even more significant and important today—18 years later—than it was when originally prepared, for the entire world looks to education for guidance and direction.

However, since Russia and the United States launched their satellites, those of us in the field of education and especially those of us teaching courses in driver education will be severely criticized for participating in a program considered by many to be a frill. The emphasis for many months to come will be on science courses, and the elimination of home economics, shop, health and physical education, driver education, and other similar courses suddenly considered nonessential in this space age will be at least debated if not accomplished.

> *Too many leading educators, through ignorance, misinformation, or inertia, consider driver education a frill and would like to see it dropped completely. Evidence shows that youths trained in driving education programs while in high school have 40 to 66% fewer violations and accidents than similar groups not so trained. Now is the time for the physician to become a real crusader for one of the most important of our school subjects—driver education—that is, if it is believed that education should be preparation for living.*

Frankly, I feel that people are emotional and are not using their heads when orating and writing about the present "needs" in education. I also believe that the main reason for the present-day cry to eliminate driver education is the fact that many Americans have little knowledge of the urgency, objectives, scope, and results of the high school driver education program.

Both former President Truman and President Eisenhower have publicly stated that traffic accidents form a major problem in the United States and have called five President's Highway Safety

---

Administrative Head, Institute of Public Safety, Pennsylvania State University, and Consultant on Driver Education, American Automobile Association, Washington, D. C.

Read in the Symposium and Panel Discussion on Motor Vehicle Accidents and their Prevention in the Session on Traffic Accidents before the Section on Miscellaneous topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

Conferences to do something about the situation. Killing 40,000 and injuring a million and a half annually is nothing less than an indictment against this great nation. Since the advent of the motor car, over 1,200,000 citizens have been killed, to say nothing of the milions seriously injured and the billions of dollars lost in property damages.

We now have evidence that youths trained in high school have 40 to 66% fewer violations and accidents than similar groups not so trained. This is ample evidence of the value of these courses and the need to extend them. And, further, think of the training in that important field of science in which chemical tests for intoxication, friction, centrifugal force, kinetic energy, gravity, motion, power, heat, light, color, and sound are discussed during the course.

We believe it is extremely shortsighted to feverishly teach many young scientists how to travel to the moon when, through lack of training in how to travel on this earth, their lives will be snuffed out completely or they will be turned into hopeless cripples before they have a chance to put their space travel knowledge to use.

We look to the educators to prepare youth for living now as well as in the future. Rather than eliminate learning in earth travel, let us increase it until every boy and every girl of legal driving age will be able to receive this instruction and driver education will assume its rightful role of importance in this age when the motor car is still very much with us. Let us cease to consider this area of education as a mere frill.

In spite of the present criticism, driver education is on the move both forward and "for good." The following progress report will serve as a basis for this statement.

Progress in Driver Education Programs

This year we are celebrating our 25th year in high school driver education. This new subject has stood the criticism, the growing pains, and everything else for a quarter of a century. The program progressed from one high school offering driver education during the 1933-1934 school term to 11,846 high schools during the 1957-1958 school term and from 20 students enrolled in that first course at State College, Pennsylvania, High School to 1,219,065 enrolled in the 1957-1958 courses. This is ample evidence that driver education is on the move and that this relatively new teaching field has the look of permanence.

Teacher Preparation.—There are over 800 college professors prepared to offer safety education courses for teachers of every grade level. This is real progress when we look back to 1937 when the first college professors' seminar in driver education was offered at the University of Kentucky.

There are over 18,000 high school teachers prepared to offer driver education courses. During the 1957-1958 school term, 453 colleges and universities offered 929 courses in safety education. This also is real progress when we look back to the summer of 1936 when Pennsylvania State University offered the first course for high school teachers in driver education.

In 1947, the State Council on Education in Pennsylvania established 12 semester hours of credit in safety education as the teacher certification requirement to teach driver education in Pennsylvania high schools. In addition, each teacher must hold a valid teaching certificate. Many of the states require the valid teaching certificate and two courses in the field of safety, one in general safety education and one in driver education. A few of the states require only a valid teaching certificate.

Organizational Programs.—Six states received the United States' top award in this field, the achievement award for the extent and quality of driver education programs conducted during the 1957-1958 school year. Six earned the progress award. This award program is conducted each year by the Association of Casualty and Surety Companies.

In 1938, when Dr. Charles Glenn was President of the American Association of School Administrators, it was decided to have a yearbook on the subject "Safety Education." Dr. Henry H. Hill was appointed chairman of the commission, and with the direction of a group of educators and safety specialists the book was released in 1940. This particular book gave visible evidence that educators were interested in safety education.

Another milestone in the development of the safety education program on a national basis was the establishment in 1943 of the National Commission on Safety Education, a division of the National Education Association (NEA). This commission gave prestige and status to the entire safety movement. Funds were made available in 1944 for the operation of the commission.

In 1949, the first conference of the new Pennsylvania Association for Safety Education (PASE) was held at Hershey, Pa. There are now close to 400 members of this association. The annual meeting offers both college and high school instructors an opportunity to exchange ideas and improve teaching methods. There are now 40 such state associations.

The presidents of the state associations met in Washington, D. C., in 1956 and formed the American Driver and Safety Education Association. The first conference was held in Philadelphia in 1957 in connection with the NEA centennial. The second conference was held at the University of Colorado, June 22-24, 1958. These conferences help the teachers improve their teaching in both the classroom and the practice driving part of the program.

The National Commission on Safety Education has arranged for three national driver education conferences. The first was at Jackson's Mill in 1949, the second at Michigan State University in 1953, and the third at Purdue University in 1958.

These national conferences are responsible for the administrative practices and policies used in driver education courses today. Thirty clock hours in the classroom and a minimum of six clock hours in practice driving for each student are standards recommended by the national conference.

Contributions.—During the 1957-1958 school term, the automobile dealers lent over 11,000 cars to schools at a value of over 24 million dollars. This is truly a significant civic activity on the part of the dealers.

Fifteen states now offer financial aid to schools when their driver education courses meet accepted standards. Bills will be introduced by other states, and in all probability 50% of the states will offer financial aid within the next five years. The details of the present plan are available from the American Automobile Association and the National Commission on Safety Education.

Teaching Techniques

The college instructors in Pennsylvania meet every year during the PASE conference to discuss ways and means to improve the safety education courses on the college level. In addition, they meet for two days in September to improve teaching materials and methods. California and Michigan also hold conferences regularly to bring the college professors together in an effort to improve their safety education courses.

Youth Driver Education.—The young people today are just as eager and anxious as adults to help solve some of the serious problems of the United States. One method that is being used successfully in the field of traffic is the holding of youth conferences; others include radio and television panels. These young people need the assistance of the driver education teachers in arranging facilities, transportation, discussion topics, speakers, and method of conducting such conferences.

For a number of years the Junior Chamber of Commerce has been sponsoring Teen-Age Road-e-os. In addition, many local areas conduct their own "road-e-os." If you cooperate in such an activity, you should make sure that every step is taken to make it of high quality. In our community, for instance, a road test is given as well as skill tests and a written test. These tests are administered by professionals in the field.

Economy Runs.—The economy run is gaining in popularity all over the nation. In most places it is conducted under the sponsorship of one oil company. However, in some places it is conducted with the cooperation of a number of oil companies and other organizations.

Adult Driver Education.—Each year over a million adults complete courses in driver education conducted by colleges, high schools, police departments, American Automobile Association clubs, commercial driving schools, motor vehicle fleets, and others. In a number of instances, the adult driver education schools are licensed by the state. Pennsylvania's commercial schools are under the supervision of the Department of Public Instruction. One of the outstanding schools for training commercial drivers is at North Carolina State College. The graduates have established an enviable record.

The Common Carrier Conference of the American Trucking Associations, Inc., is making plans to have vocational schools conduct courses for commercial drivers. This is now being done at Washington High School in Los Angeles.

The National Committee for Motor Fleet Supervisor Training, working cooperatively with over 50 colleges and universities, has prepared over 15,000 supervisors who have under their direction over 2 million drivers. Another forward move is the directive from Air Force Headquarters in Washington, D. C., requiring every airman 25 years of age and under to complete 10 hours of instruction in driver education. These different programs are certainly indications that driver education is on the move.

Driver Licensing and Preparation.—In Connecticut and Michigan, laws have been passed requiring boys and girls to complete in a satisfactory manner an approved course in driver education in order to get a license at 16 or 17 years of age. There is also considerable agitation for more junior license laws which would require approved courses and would permit driving only at certain hours without adult supervision.

There are a number of states that now permit boys and girls to practice in the school car with the approved instructors six months or a year before the age at which a license can be obtained. According to reports from the instructors, preference is given to the six-month period because there is too long a gap in a year's interval between course completion and the examination for a license.

Teachers, in general, do a fairly good job when conducting their driver education courses. However, there is always plenty of room for improvement. One of the big problems is the cost for the practice driving part of the program. Efforts are being made to cut this cost. One method is to use simulators, such as the American Automobile Association Auto Trainer or the Aetna Drivotrainer. Those who have made studies of the use of these devices say that they reduce significantly the amount of practice time. Some experiments showed that pupils with 12 hours practice first in a simulator reduced the actual behind-the-wheel time from six to three hours. Of course, we must consider equipment costs and the cost of the space for the simulators. But, in the long run, the cost per pupil should be less.

Other plans to help with the practice driving have included use of cadet teachers, high school seniors, and school bus drivers. In most instances, these plans are not very satisfactory because such persons are not professional teachers. Some instructors use flash film, commentary driving, or the discussion-decision technique to improve driving practice experience and to shorten time and costs.

In Michigan, the multiple-car plan is used quite extensively for the practice driving part of the program. One instructor, through the use of a public address system, or car radios, can handle from 6 to 12 cars on the driving range. The driving range usually includes signs, signals, markings, one-way streets, curves, parking stalls, and other traffic patterns found in regular driving.

It is quite evident from these different plans that a variety of approaches are being used to reduce the cost of the program and still produce good drivers.

Supervisors in Safety Education.—Twenty-five years ago we could have counted on the fingers of one hand the number of cities and states having a full-time supervisor in safety education. Today, practically every city and community, as well as every state, has at least one individual assigned full time or part time to safety education in the school system. In some instances, there is a full time staff worker in driver education alone. When this is the case, the program has acceptance by top educators.

Scientific Advancement

We are all aware of the research dealing with seat belts and harness, padded instrument panels, recessed steering posts, padded sunvisors, shatterproof glass in rear-view mirrors, special door latches, rearward seating, and, finally, the safety car with the driver in the middle and without a steering wheel. Such developments will most certainly affect our teaching.

We also know that it is now possible to keep a car in its own lane automatically and to warn drivers of impending dangers, such as curves and fog, electronically. Research in these fields will continue because of the help such installations will offer in reducing traffic accidents.

Conclusions

One of the big problems in driver education today is getting the acceptance and approval of top educators. Too many leading educators, through ignorance, misinformation, or inertia, still consider driver education a frill and would like to see it dropped completely. Others advocate its being scheduled as a vocational subject or conducted during the suggested 13th year in the public schools.

I believe such problems help us because we are now forced to stand up and speak out just as positively in favor of driver education as others are speaking negatively about this program. Please let your voice be heard in public. Now is the time to become a real crusader for one of the most important of our school subjects—driver education—that is, if you believe that education should be the preparation for living. We are counting on your help, not only as citizens and parents but as a group of people welded into one of the most effective of all organizations for combating human misery—the medical profession. We enlist your aid.

I would like to close with this basic concept concerning traffic, one that offers great hope in reducing the all-too familiar traffic accidents: Our greatest potential for achieving smooth, safe, orderly, and efficient movement of traffic is through a driver education program in every high school that reaches every boy and girl prior to the time when they become legally old enough to be licensed to drive.

This, then, is the long-range program that will eventually offer the greatest contribution to the development of good traffic citizenship. It doesn't cost to teach them to drive—it pays.

CHOLESTEROL PRESENT IN ALL CELLS.—Cholesterol is an alicyclic unsaturated alcohol present in all animal cells and in blood. It is the characteristic sterol of animals, the plant sterols having additional carbon in the side-chain. In the body, cholesterol functions as a precursor of the bile acids and of numerous hormones of the adrenals and gonads. Cholesterol itself is a constituent of lipoproteins and both in serum or in tissues may occur either free or esterified by fatty acids. . . . As well as being absorbed from food, cholesterol is synthesized in the animal body, as was shown quite early by feeding experiments. The liver is an important site of synthesis and appears to be the principal endogenous source of the cholesterol in blood plasma. Many other tissues are also known to synthesize the sterol: the intestinal mucosa, ovary, and all foetal tissues of the rabbit; the theca interna, theca externa, and zona granulosa of the hen's ovary; the adrenal cortex, kidney, the testis and skin are all sites of active synthesis.—J. W. Cornforth, M.Sc., D.Phil., F.R.S., and G. Popjak, M.D., F.R.IC, Biosynthesis of Cholesterol, *British Medical Bulletin*, September, 1958

THROMBOPENIC PURPURA AS A COMPLICATION OF MUMPS

Charles P. Kolars, M.D.
and
Wesley W. Spink, M.D., Minneapolis

Three adults with mumps had thrombopenic purpura as a serious sequela. Thrombopenia must be added to orchitis and meningoencephalitis as a complication of this not uncommon infection in adults. Although direct invasion of the tissues by virus may be responsible for the inflammatory reaction, the possibility also exists that a state of acquired hypersensitivity may be the cause. Steroid therapy is helpful in thrombopenia occurring as a complication of mumps.

Thrombopenic purpura and nonthrombopenic purpura are occasionally observed in patients with infectious diseases. Clement and Diamond[1] reported on the findings in 96 children with thrombopenic purpura. In 65 of these children the purpura was associated mostly with upper respiratory infections, but it occurred also as a complication of rubella, chickenpox (varicella), and infectious mononucleosis.

We are presenting the clinical course of three adults with mumps who had thrombopenic purpura as a serious complication. In reviewing the literature, we have been unable to find any documented instance of this complication occurring with mumps. Perhaps thrombopenic purpura appears more frequently in mumps than is realized, since the three patients were seen over a relatively brief period of time. Further emphasis should be given to this complication because of the difficulties encountered in controlling the bleeding.

Report of Cases

Case 1.—A 65-year-old woman entered the University Hospitals on March 7, 1955, because of bleeding. Having always enjoyed good health, the patient developed an occipital headache six weeks prior to admission. A week later parotid swelling appeared, which was soon followed by epistaxis and "red spots all over the body." Within the next few weeks, lethargy was associated with vaginal bleeding, hematuria, and ecchymoses.

Her only medicaments were salicylates and an iron preparation. Of considerable significance was the fact that just prior to her illness she had had close contact with several members of her family, including children, who had mumps. She was not certain of having had mumps previously. There was no history of a bleeding tendency. Her family history was irrelevant.

Physical examination revealed an obese woman with a normal temperature and pulse rate and a blood pressure of 165/85 mm. Hg. There was a fresh hemorrhage in the left ocular fundus. A grade 2 systolic murmur was heard over the precordium. The liver and spleen were not palpable. There was a generalized petechial eruption of the skin over the entire body, especially the legs.

The pertinent laboratory data revealed 3+ erythrocytes in the urine. Hematological data showed a hemoglobin level of 14.0 Gm. %, erythrocytes, 4,210,000 per cubic millimeter, leukocytes, 5,800 per cubic millimeter with 68% neutrophils, 27% lymphocytes, and 5% monocytes, platelets, 18,000 per cubic millimeter, a bleeding time greater than 15 minutes, and a clotting time of 5 minutes, with only a slight retraction of the clot in 17 hours. The prothrombin time was normal. The cuff test gave positive results. The reticulocyte count was 4.9%, and a section of sternal bone marrow showed a marked increase in megakaryocytes. Findings on the direct and indirect Coombs' test were negative. The four-day fecal urobilinogen excretion was normal. The complement-fixation test for mumps showed positive results in a dilution of 1:64. The L.E. cell test was negative. Liver function tests were normal except for a 3+ cephalin flocculation.

Because of the diffuse bleeding and the scarcity of peripheral platelets, she was given 200 mg. of cortisone orally for the first three days. No improvement occurred, and for the three following days 400 mg. of cortisone was administered daily. The daily intake of cortisone was then reduced to 300 mg. Because only 18,000 platelets per cubic millimeter were present and because of continued hemorrhage, splenectomy was carried out on March 18, 1955, after preparation with one unit of whole blood. The resected spleen weighed 180 Gm. and appeared normal, grossly and histologically. Cortisone therapy was continued. Two days after operation the platelets numbered 144,000 per cubic millimeter. The cortisone intake was reduced to 150 mg. daily on March 23, at which time there were 371,000 platelets and 18,000 leukocytes per cubic millimeter. The dose of cortisone was gradually reduced, and this therapy was discontinued on March 25, at which time 15 units of ACTH was administered. At this point there were 765,000 platelets per cubic millimeter. The platelet level then gradually stabilized at 90,000 to 100,000 per cubic millimeter. She was discharged from the hospital on April 6, 1955, after an uncomplicated postoperative period. She has had good health up through the last follow-up examination on June 10, 1958.

Comment.—This elderly woman undoubtedly had mumps with thrombopenic purpura as a complication. The number of platelets remained low through the period of steroid therapy, and splenectomy was followed by only a transient rise in the platelet level.

Case 2.—A 27-year-old woman was admitted to the University Hospitals on March 15, 1957. On Dec. 7, 1956, she was seen by her physician because of fever and parotid swelling. A diagnosis of mumps was made. There had been an exposure to the disease three weeks previously. Ten days after the onset of the parotitis, a petechial eruption appeared over the lower extremities, and thrombopenia was found to be present. She was admitted to a hospital on Dec. 18, 1956

From the Department of Medicine, University of Minnesota.

and given 300 mg. of cortisone daily for three weeks. The platelet count approximated 25,000 per cubic millimeter during this time. The cortisone dosage was reduced to 150 mg. daily on Jan. 19, 1957, and this therapy was continued for several weeks.

Because the platelet level failed to rise, she entered the University Hospitals for splenectomy on March 15, 1957. Further questioning at this time revealed that she had taken only salicylates prior to the onset of thrombopenia. There had been no previous history of her having had mumps. On examination she had an appearance resembling that seen in adrenal cortical hyperfunction (Cushing's disease). The temperature and pulse rate were normal, and the blood pressure was 120/70 mm. Hg. There was an acneiform eruption over her face and shoulders, and a few abdominal striae were present. The liver and spleen were not palpable. A few scattered petechiae were present on the legs.

Significant laboratory data showed a hemoglobin level of 12.4 Gm. %, leukocytes, 8,550 per cubic millimeter with 75% neutrophils, and a platelet count of 23,000 per cubic millimeter. The bleeding time was 10½ minutes and the clotting time 3½ minutes. The reticulocyte count was 2.2%. Clot retraction was normal. Normal serum protein values were found. The serum iron level was less than 20 μg. per 100 ml. Findings on three L. E. cell tests were negative. The direct and indirect Coombs' test results were negative. The complement-fixation test for mumps showed positive findings in a titer of 1:32. A four-day fecal urobilinogen excretion was normal. Sternal bone marrow aspiration on March 19, 1957, revealed a normal number of megakaryocytes, but they were morphologically abnormal in appearance.

On March 22, cortisone therapy was discontinued and she was given 40 mg. of prednisone daily. The platelet levels continued to fluctuate between 16,000 and 80,000 per cubic millimeter. Splenectomy was carried out on April 10, 1957. The spleen weighed 150 mg. and grossly and microscopically appeared normal. The platelet count just prior to surgery was 54,000 and 12 days later 826,000 per cubic millimeter. The steroid intake was gradually reduced, and this therapy discontinued on April 30, at which time the platelet count was 630,000 per cubic millimeter. When she was discharged on May 7, 1957, the platelet count was 450,000 per cubic millimeter. On follow-up visits it was observed that the thrombopenia had returned. On June 4, 1957, the platelet count was 80,000 per cubic millimeter and steroid therapy was resumed. By June 11, the count was 164,000. Over the succeeding weeks steroid therapy was gradually reduced and finally discontinued on Sept. 3, 1957. At this time the platelet count was 282,000 per cubic millimeter. When last seen on Feb. 4, 1958, she was in good health and the platelet count was 275,000 per cubic millimeter.

Comment.—The foregoing case report emphasizes the seriousness and chronicity of thrombopenia occurring as a complication of mumps. Steroid therapy did not abolish the thrombopenia, but it was helpful in controlling the bleeding tendency. Again, splenectomy failed to achieve any sustained rise in the platelet count.

CASE 3.—A 44-year-old man was admitted to the University Hospitals on April 1, 1958, because of bleeding gums and a generalized petechial eruption over the skin of his body. Seven days prior to admission he had had a severe headache, which was followed two days later by parotitis. Two of his children, aged 5 and 6 years, had had mumps three weeks before the onset of his illness. On the day before entry to the hospital he had noted right testicular pain and tenderness. On the morning of admission he had bleeding of the gums and observed a generalized petechial rash.

The only medicament he had taken prior to his illness was a salicylate. There was no history of mumps. For a number of years he had had a scaly erythematous rash over his cheeks which appeared each spring and fall. He had episodes of wheezing during the ragweed season.

Physical examination revealed a well-developed and well-nourished white man with a normal temperature and pulse rate and a blood pressure of 108/75 mm. Hg. No parotid swelling was present. The liver and spleen were not felt. The right testis was enlarged and quite tender. A severe petechial eruption was present on the skin of his neck, hard palate, arms, and legs.

The laboratory data revealed occasional erythrocytes in the urine. The hemoglobin level was 14.1 Gm. %, leukocytes, 6,800 per cubic millimeter with 66% neutrophils; platelet count, 12,000 per cubic millimeter, and prothrombin time, normal. A study of aspirated sternal bone marrow revealed slight hypoplasia with a moderate increase in the number of megakaryocytes. The complement-fixation titer for mumps was 1:128.

During the first six days of hospitalization, the platelet counts fluctuated between 8,000 and 34,000 per cubic millimeter and petechiae continued to appear. Beginning on April 7, 1958, 60 mg. of prednisone was given daily. Within 48 hours the painful orchitis had subsided, and by April 16 the platelet count rose to 110,000 per cubic millimeter. The dosage of prednisone was gradually reduced to 35 mg. daily, but further reduction was followed by a diminution in the number of platelets. On April 24, the platelet count was 52,000 per cubic millimeter and the dosage of prednisone was increased to 45 mg. daily. During the following three weeks the maximum platelet count was 95,000 per cubic millimeter. On May 15, 1958, the dosage of prednisone was reduced, so that by June 5, 1958, the platelet count had stabilized at about 100,000 per cubic millimeter. Finally, on July 7, 1958, the prednisone therapy was discontinued, the platelet level being 139,000 per cubic millimeter. He was asymptomatic.

Comment.—This man had two acute complications of mumps, orchitis and thrombopenia. The hemorrhagic tendency was serious, but persistent steroid therapy controlled the bleeding. It is interesting that, although splenectomy was not carried out in this patient, the natural course of the thrombopenic state was similar in character to that in the other two patients.

Summary and Conclusions

Mumps is not an uncommon infection of adult life. The complications can be painful and serious; they include orchitis and meningoencephalitis. Less commonly, pancreatitis and oophoritis occur. Thrombopenia must be added as a complication, and this is potentially serious. The pathogenesis of these complications is not clearly understood. Although direct invasion of the tissues by virus may be responsible for the inflammatory reaction, the possibility also exists that a state of acquired hypersensitivity may be the cause.

There is now substantial evidence showing that the inflammatory complications of orchitis and meningoencephalitis can be controlled by therapy with adrenocorticosteroids.[2] The present report indicates that steroid therapy is also effective in thrombopenia occurring as a complication of mumps. In two of the three patients steroid therapy was insufficient to correct the platelet deficiency but did control the bleeding tendency. In a third patient with orchitis and thrombopenic purpura, steroid therapy alone controlled both complications. It is suggested that mumps should be considered as a possible causative factor in cases of "idiopathic" thrombopenic purpura. The clinical course of these three patients suggests that splenectomy was not definitive in terminating the thrombopenic state. Steroids did control the bleeding tendency.

OBJECTIVES FOR STATE MEDICAL SOCIETY TRAFFIC SAFETY COMMITTEES

John R. Rodger, M.D., Bellaire, Mich.

It is my belief that every state medical society should have an active traffic safety committee or should assign a traffic safety program to some appropriate existing committee of the state society. The Committee on Medical Aspects of Automobile Injuries and Deaths of the American Medical Association can develop suggested health standards for driving automotive vehicles, but these standards must be tailored to the individual needs of the separate states. Fortunately or not, the legal problems attendant on driving on the highways of the United States are functions of state governments rather than of the federal government. Educational campaigns to improve driving abilities are largely effective on a state basis. For this reason the successful cooperation of the medical profession in the field of traffic safety will be even more dependent on what state medical societies do than on what the A. M. A. does.

The cooperation of the medical profession is needed in the field of traffic safety, and effective leadership can be supplied by committees appointed by state medical societies. Their function should be to guide and stimulate; they can supply needed information to interested groups, seek to improve existing laws that affect automobile traffic, and cooperate in special projects of research and education. In addition to carrying out the strictly medical aspects of its activities, a traffic safety committee can do much to promote programs of training for student and adult drivers, supplement the efforts of civic groups and governmental agencies, and, in general, set good examples of driving habits, law observance, and good citizenship.

What can a state medical society do about this problem? I say "state medical society" rather than just the traffic safety committee of a state medical society, for success will come only as all the members of a state medical society contribute to meeting the problem under the leadership of a traffic safety committee. The job of the committee is to guide and stimulate. By itself, it can do little.

How large should such a committee be, and who should be on it? Five should be a minimum number. A committee of over 10 or 12 members becomes unwieldy. Interested members should come from many fields of medicine, not just one or two. Such areas would include general surgery and its subbranches most interested in trauma, general practice, internal medicine, eye, ear, nose, and throat, psychiatry, public health, and other related fields.

Such a committee may well spend one meeting or more just in finding out what the traffic situation is in that particular state, determining statistics, finding out something about the more important existing traffic laws, and meeting with a representative of the state police and state driver licensing agency. It will soon discover that there are many others just as interested in this traffic safety problem as physicians are and that the job is a cooperative one with no easy answers and no one master solution. The members of the committee will find that there is an avalanche of facts and present programs about which it knows very little. After looking over the field carefully, it should then settle on one or two projects at a time which are necessary and

---

Chairman, Study Committee for Prevention of Highway Accidents, Michigan State Medical Society.

Read in the Symposium and Panel Discussion on Motor Vehicle Accidents and Their Prevention in the Session on Traffic Accidents before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

reasonably attainable within a few years at most. All progress is agonizingly slow to those who are enthusiasts!

There is a large group of medical and a smaller group of nonmedical projects which such a committee might consider in view of the primary needs in an individual state. The following objectives are offered as suggestive only and not as all-encompassing.

Medical Objectives

The committee should first aim to provide the practicing physician with technical medical information regarding driving limitations for his patients. This can be done by drawing attention to (1) the A. M. A. manual soon to be published: "Medical Guide for Physicians in Determining Fitness to Drive a Motor Vehicle"; (2) special traffic safety editions of the state medical society journal, with the authors of the articles primarily, but not necessarily, from that state (the authors need not all be doctors); a recent such issue of the *Journal of the Michigan State Medical Society* contained articles with the following titles: "Are Your Patients Physically Qualified to Drive?" "Use of Chemical Tests for Intoxication in Michigan Law Enforcement," "Drugs and Driving," "The Highway Accident Problem in Michigan and What Has Been Done About It," "Automotive Crash Injury Research in Michigan," "Traffic Accidents and Safety," "The Speeding Ambulance," and "Emotional Problems in Driving"; (3) both intramural and extramural postgraduate courses for practicing physicians in both prevention and treatment of traffic injuries; and (4) appropriate information through the secretary's letter as well as other special media from the office of the state medical society.

The second objective should be to inform the driving public, through the use of proper media, of those medical conditions which may adversely affect driving proficiency. This can probably be done best by an effective distribution of the A. M. A. booklet, "Are You Fit to Drive?" either by the state medical society alone or in cooperation with other interested groups, such as industrial and insurance companies. Placement in local offices for driver licensing would be most effective if enough copies are available. Information to the public can also be given through the usual media of the press, television, radio, luncheon clubs, parent-teacher associations, and other groups. And let us not forget one of the most important means of all, i.e., individual contact with our patients!

Third, the committee should become familiar with the individual state's driver licensing laws and seek to improve them. This is a long, slow process and will not be accomplished overnight. It may take repeated years of introduction of legislation before it even gets out of a legislative committee and more years yet before it becomes law in an unemasculated form.

Fourth, the committee should cooperate with special projects, such as the Cornell Crash Project and other programs of medical research in the traffic safety field. This will mean work, but it will yield results that can be gained in no other way. The facts of traffic epidemiology and research should guide our efforts.

Fifth, the committee should seek to encourage the teaching of first-aid courses. Such courses, if they are to receive Red Cross recognition, must be taught either by trained lay instructors or by physicians.

Sixth, the committee should promote state and municipal standards for ambulance operators and equipment. Flint, Mich., has such regulations, and the Michigan State Medical Society is considering legislation of this type for possible introduction in the next session of the legislature.

Seventh, the committee should cooperate with state departments of public instruction in the securing of adequate health standards for school bus drivers.

Eighth, the committee should seek to promote, particularly in the larger county societies, traffic safety committees for county medical societies.

Nonmedical Objectives

There are several nonmedical fields of traffic safety in which it is advantageous and proper for a state medical society to lend its cooperation, even though in most instances the more strictly medical fields should receive a first priority of time and effort.

First, inclusive student driver training legislation should be a goal for each state. Comparison studies have pointed up the fact that students who have passed behind-the-wheel student driver training courses in high school have approximately one-half the accident rate of those who have not. In most states at least one-fourth of all traffic fatalities involve drivers 25 years of age and under, and in some states this figure is closer to one-third. In all the public schools of the United States, just over one-third of the students reaching legal driving age are able now to take behind-the-wheel driver training. Total figures for the private and parochial schools are not available, but they are undoubtedly much less than the one-third mention for public schools.

Benefits from a comprehensive student driver training program would be cumulative from year to year in this younger age group, probably averaging a total reduction of approximately 8% in the over-all traffic death rate when the program has been in existence for 10 years and allowing for a one-third coverage at the present time. Based on the total annual traffic toll of 38,000, this would mean a reduction of 300 deaths the first year, with increased savings of an additional increment of 300 lives each year until approximately 16,500 lives would be saved over a 10-year period. At least a part of the marked drop in traffic fatalities in Michigan over the past two and one-half years (over 25%) has been attributed to an inclusive driver training program.

Traffic experts say that the attitudes of individual drivers play a large part in the accident picture. Nowhere is there a better chance to develop, en masse, good attitudes along with the technical skills than in a comprehensive program of student driver training, for such courses must be taught by trained teachers with minimum standards for the subject material and the amount of time behind the wheel.

What is envisioned in such a comprehensive program? Michigan legislation requires that each teenager must wait until he is 18 to get his driver's license unless he has first passed an approved student driver training program, in which case he may get his license at the age of 16. This is the carrot in front of the donkey that gets the students into the courses! Every public high school must offer the course if it is requested by students.

In return for the fact that driver education is more expensive per pupil than other courses offered in high school, the state subsidizes the schools approximately $20-$25 per pupil, this money being secured by earmarking 50 cents a year from the driver license fee. Without some such subsidy, the schools, for the most part, would not be able to finance comprehensive training coverage, and it seems fair for those driving on the highways to help insure the young drivers becoming safer drivers. The young driver himself will have repaid the cost of his subsidy after paying for his driver license fees over a 45-year period.

In Michigan, private and parochial students who want to take the course may do so at a nearby public high school, with the public high school receiving the subsidy.

In the current critical examination of school curriculums, the place of driver education has been attacked by some, including Mr. Adlai Stevenson. I am sure that Mr. Stevenson and the other critics have not examined the available statistics on the problem. Furthermore, it is not necessary that basic subjects be sacrificed for driver education. The small high school in my community requires 20 units instead of the customary 16 for graduation, and 16 of these 20 must be in basic subjects. In Jackson, Mich., the extra time for driving is taken from physical education and not from basic subject time. Many of the larger high schools conduct courses in the summer for those unable to take them during the school year. Our future scientists will not suffer for being taught driver education while in high school, and, because of this training, they will stand a greater chance of staying alive long enough to be scientists! There is no hint that school critics would toss physical education out of the curriculum, and yet in terms of conservation of human life we must conclude that there is an even greater potential in a comprehensive student driver training program than in a physical education program.

Second, we should also urge the formation of special schools for adult driver training and for chronic traffic offenders. This is already being done in some states, including the state of Michigan, with schools organized on a fee basis which meets all their costs and adults either going voluntarily or being sent there by the courts for remedial instruction.

Third, we should cooperate actively in state and local citizens' traffic safety committees. Such committees are eager for support, on many issues they need our advice, and on safety matters of public education and proposed legislation we may need theirs! A citizens' traffic safety committee is much like a military division which is composed of different types of troops, not all of whom may be in action at the same time but who still need each other's support. We also must not forget that, as doctors, we also are citizens and have responsibilities apart from our profession.

Fourth, we should early offer the facilities of the state medical society to the governor, the state police, the state's licensing authority, and any other governmental agency on the state or local level which is attempting to meet the traffic safety problem. I scarcely need to point out that a by-product of these activities can be excellent public relations to the profession in the state.

Fifth, we should discipline ourselves and encourage our colleagues to set good examples in driving habits and law observance. There are times when, perhaps, it seems necessary for us to go faster than the speed limits and to take chances, yet, like a speeding and red-light crashing ambulance which kills more lives than it saves, the speeding doctor may be more of a health hazard than a health protector at times! Let us take the two-by-four out of our own eye before we start looking for the splinter in the other driver's eye!

Conclusions

A traffic safety committee of a state medical society must be more than just a window-dressing committee. It should carefully examine possible courses of action and programs for the society to undertake. The committee members and the society members they represent should come to see that, like anything else of value, a worthwhile traffic safety program will cost something in terms of time, effort, money, and sometimes, perhaps, even changed attitudes.

Finally, we can take the advice which Stonewall Jackson once gave to his younger officers: "Never underestimate yourself in action; never overestimate yourself in the official report."

USE OF PROMETHAZINE (PHENERGAN) HYDROCHLORIDE IN OBSTETRICS

REPORT OF A TWO AND ONE-HALF YEAR SURVEY

John J. Carroll, M.D., C.M.
and
Robert S. Moir, M.B., Ch.B., Vancouver, British Columbia, Canada

Sedation and analgesia during the first stage of labor have been induced in more than 7,500 obstetric patients during a two and one-half year period by a regimen involving use of promethazine (25 to 100 mg. by deep intramuscular injection) and meperidine. The hospital charts of these patients have been compared with those of obstetric patients, during the two and one-half years before promethazine was used, with respect to maternal, fetal, and neonatal mortality, prematurity, duration of labor, and frequency of need for resuscitating the infant. The data showed that promethazine was a safe and effective tranquilizer, rendered labor less unpleasant, and reduced the need for those analgesics and anesthetics which have undesirable side-reactions. A shortening of labor was found and was particularly significant in uncomplicated primiparous cases. Resuscitation of the infant was almost never necessary. The average total dose of promethazine was 56.5 mg., and its effect in reducing the total amount of meperidine needed was convincingly demonstrated.

Our efforts to improve present methods for relief of pain of normal labor, as well as for management of dystocia, and at the same time to reduce perinatal mortality have led us to investigate a number of compounds credited with a relaxant action on the cervix. It is a common observation that labor is more difficult and dilatation unusually slow in the frightened, tense, and highly emotional patient.

Psychological preparation for parturition, although an important factor in prenatal care, has limited usefulness as the sole means of managing labor and delivery. Hypnosis is suitable for few patients, and the "childbirth without fear" concept popularized by Grantly Dick-Read is satisfactory for only about 25 to 30%, according to this author himself. In the great majority of cases, therefore, analgesic and sedative drugs are the only recourse. No drug, however, satisfies all criteria: (1) no increase in risk to parturient and fetus, (2) no interference with the labor mechanism, (3) no clouding of the mental faculties of the patient, (4) convenience of administration, and (5) promptness of action. All conventional agents, such as barbiturates and narcotics, are readily transmitted through the placental circulation, with well-known deleterious effects, and, in dosages within the limits of safety for the fetus, they are usually far from adequate for the needs of the mother.

Since fear-induced discharge of epinephrine increases the cervical tonus, we tried, in our parturient patients, to block the release of epinephrine with agents that depress the sympathetic nervous system (dihydroergotamine, dihydroergocornine, and similar substances). The use of these agents has now been largely abandoned in this hospital, and greater attention has been directed toward the potentialities of the various phenothiazine compounds with suppressive activity on the reticular formation of the central nervous system. Animal experiments[1] have shown that chlorpromazine hydrochloride (in doses of 3 to 6 mg. per kilogram of body weight) prevents the altering response to pain and that promethazine hydrochloride (in doses of 5 to 10 mg. per kilogram) produces the same effect.

Our first report[2] described the results of clinical studies employing combinations first of chlorpromazine with meperidine hydrochloride and then of promethazine with meperidine for sedation and analgesia during the first stage. The action of chlorpromazine proved most unpredictable, and labor appeared prolonged. The patients in whom adequate sedation was achieved showed evidence of decreased muscle tone; such limpness was believed partly to account for the increased duration of labor. Combination of promethazine with meperidine, on the other hand, was highly effective and produced results as predictable and analgesia as satisfactory as with twice the dose of meperidine alone. In consequence of these initial trials, more than 75% of the obstetricians and general practitioners on the staff of this hospital now use promethazine and meperidine in varying combinations for routine sedation during labor. Since predelivery medication is administered entirely at the discretion of the attending obstetrician, there is considerable variation in the volume and timing of the doses. In some cases both meperidine and promethazine are administered together; in others, the doses are administered in succession, from one-half hour to two hours apart. Single doses of each agent range from 25 to 100 mg. Promethazine is always administered by deep intramuscular injection.

Director, Department of Anesthesia (Dr. Carroll), and Fellow in Anesthesiology (Mr. Moir), Grace Hospital.

Since the publication of our first report,[2] more than 7,500 obstetric patients have been given sedation under this regimen. We have reviewed their charts and compared them with those of the patients in whom delivery was performed in the two and one-half years prior to the use of promethazine. All cases of infant morbidity and fetal and neonatal deaths have been reviewed in detail (tables 1, 2, and 3); also, the records of 263 consecutive unselected patients given this sedation in 1957, who were delivered of 265 infants (including two pairs of twins), were studied in detail. The results of these reviews will be presented here. We believe they will provide an adequate picture of the over-all results.

Description of Series and Drug Administration

More than 7,500 patients were treated with promethazine. The neonatal and fetal mortality rates were not appreciably altered (table 1), and, in all, maternal sedation and anesthesia can be ruled out as a cause of death. The pulmonary neonatal morbidity, however, has shown a definite improvement. The decrease in neonatal pulmonary morbidity we attribute to reduction in the amount of respiratory-depressant agents (such as narcotics and barbiturates) required to control the discomforts of first-stage and second-stage labor and decrease in the level of general anesthesia necessary for delivery. During the past two and one-half years (July, 1955, through December, 1957), since the obstetric use of promethazine was initiated, the need of infant resuscitation has become so rare that the members of the resident staff have complained they are getting no training or experience in this important phase of infant care.

Paradoxically, with the decrease in the amount of narcotics used labor rooms have become quiet and peaceful. Except in the cases managed by the few physicians who do not prescribe promethazine, it is most unusual to hear patients in labor crying or complaining bitterly of their pains. The elimination of apprehension not only has reduced the discomfort of the patients but has enabled the case room staff more easily to evaluate their progress and has lessened the tenseness, fatigue, and irritability of the nurses in charge.

A detailed study of 263 consecutive patients treated with promethazine was made. Of these patients, 46% were primiparas. Ages ranged from 14 to 44 years.

Pregnancy had proceeded without incident in 214 (81%). Complications in the remainder included two cases of preeclamptic toxemia. Moderate to excessive vomiting during pregnancy had occurred in 17 patients.

Gestation was of normal duration in 89%. In 3% labor was premature, and 8% of the patients went into labor at 41 to 43 weeks.

On admission, about 75% appeared calm or were able to conceal their natural nervousness and fear of pain, while the other 25% were openly frightened and apprehensive.

Dosage.—Medication was usually administered according to the plan followed in the initial study; i. e., when the patient began to complain unduly of her discomfort, 25 to 50 mg. of promethazine and 50 mg. of meperidine was administered intramuscularly regardless of the extent of dilation. Thus, many patients, especially older primiparas and those whose labor was associated with complications (23 patients), received the initial dose early in the first stage. The dose was repeated at

the discretion of the labor room nurses or according to the individual physician's orders and, occasionally, if indicated, in an amount larger than that used initially. Although we discouraged the use of other agents, a few obstetricians, in rare instances, supplemented the medication with a small dose of some other narcotic or barbiturate.

For the individual patient the total dosage of promethazine ranged from 25 mg. (14%) to 125 to 150 mg. (5%). Fourteen per cent required 75 mg. and 11% 100 mg. The majority (56%) obtained adequate sedation with 50 mg. In uncomplicated cases meperidine was required for analgesia in total doses of 25 to 200 mg. Eighty per cent received 50 or 100 mg. In protracted cases with abnormalities of presentation or other difficulties and in trial labor, pain was adequately relieved in 50% with 50 or 100 mg. of meperidine. The remainder received 125 mg. or more, and 275 mg. was required by two patients (table 4).

Although most patients (61%) received the last dose of meperidine one to two hours before delivery, the timing of this dose ranged from eight minutes to 18 hours before delivery.

For the entire 263 patients, the average total dose of promethazine was 56.5 mg. and of meperidine 93.7 mg. (table 5).

Results

Average Duration of Labor. In uncomplicated cases, the average length of the first stage, for primiparas, was about 11 hours and of the second stage about 35 minutes. The total length of uncomplicated first-stage and second-stage labor for primiparas averaged 11 hours and 35 minutes. For the multiparas in this group, the first stage averaged seven hours, 30 minutes, and the second stage 20 minutes. The total length of uncomplicated first-stage and second-stage labor in the multiparas averaged seven hours and 50 minutes (table 6).

* Four patients.

For difficult and protracted cases, in which rotation and delivery with midpelvic forceps was required, the total duration ranged from 15 hours and 10 minutes to 55 hours and 15 minutes, with an average of approximately 27 hours and 50 minutes.

Trial labor, conducted in five primiparas, ranged from 8 to 34 hours and averaged 26 hours and 23 minutes (table 6).

Presentation.—Eighty-eight per cent of the fetuses were in cephalic presentation. Difficulties in descent and abnormalities of position and presentation, such as transverse lie, transverse arrest, and shoulder dystocia (two cases), occurred in 6%. The breech presentation occurred in 3%. In the remaining 3%, cephalopelvic disproportion, small outlet, deep transverse arrest, and presence of Bandl's constriction ring (in a 31-year-old primipara) necessitated cesarean section.

Anesthesia.—Delivery was performed in 71% of patients with uncomplicated cases under general anesthesia. Intermittent inhalation of nitrous oxide and oxygen was used for analgesia during painful second-stage contractions; for delivery, deeper anesthesia was induced with cyclopropane or trichloroethylene. The average duration of general anesthesia was about 38 minutes. Peridural anesthesia was used in 28% of patients. Two multiparas were delivered without use of anesthetic agents.

Table 5.—*Potentiation of Analgesic Action of Meperidine by Promethazine*

	Patients, No.	Promethazine, Av. Total Dose per Patient, Mg.	Meperidine, Av. Total Dose per Patient, Mg.
Routine sedation in controls (prior to use of promethazine)	435	...	156.8
1955 series	300	38.5	93.0
1957 series	263	56.5	93.7

Rotation and delivery with midpelvic forceps was performed with the patient under anesthesia with nitrous oxide and trichloroethylene (six patients) or under peridural anesthesia (nine patients). Average duration of anesthesia in this group was about one hour and five minutes.

Cesarean sections were performed with the patient under subarachnoid block anesthesia with use of tetracaine hydrochloride.

Delivery.—Delivery was spontaneous in 50% of the patients (28 primiparas, 104 multiparas), and for 42% low forceps were used (77 primiparas, 33 multiparas), in a few cases after manual rotation. For 5% (10 primiparas, 5 multiparas) midpelvic forceps rotation and delivery were required.

In 55% of patients with vaginal deliveries episiotomy was performed (87 primiparas, 57 multiparas), and 6% of patients experienced lacerations. The umbilical cord was wound around the neck of the fetus in five cases. The placenta was retained in two primiparas; manual extraction was performed in one of these after one-half hour. Of the eight cesarean operations (3%), one was a repeat section.

Mortality.—There were three antenatal deaths (a fetal mortality of 1%). One was in a stillborn female, delivered spontaneously with shoulder presentation, of a 35-year-old multipara at 42 weeks' gestation. Labor was medically and surgically induced 48 hours after rupture of the membranes. Death was attributed to intrauterine pneumonia, intramedullary adrenal hemorrhage, and septicemia. The second was in a stillborn male of a 26-year-old multipara by spontaneous vertex delivery after 26 hours' labor at 40 weeks' gestation. Death was believed to be the result of placental separation, since no fetal heart sounds had been detectable for two days prior to induction of labor. The third fetus in this group was aborted at 28 weeks' gestation; the mother was a 26-year-old primipara. There were no maternal deaths.

Infants.—Ninety-five per cent of the 262 viable infants breathed and cried spontaneously within one minute of delivery; 3.5% required mild resuscitation with removal of mucus from the pharynx and administration of oxygen by mask, and 1.5% (four infants) showed some respiratory depression and received, in addition to oxygen in positive-pressure breathing, intravenous injection of a narcotic antagonist (nalorphine hydrochloride, 0.2 mg.).

One child in the latter group was delivered with low forceps, with the mother under peridural anesthesia for 60 minutes, after 21 hours and 50 minutes' labor. The mother had received a total of 150 mg. of meperidine and 100 mg. of promethazine during labor. In the second case, the umbilical cord was wound around the neck; transverse arrest and shoulder dystocia necessitated forceps rotation and delivery with the mother under peridural anesthesia for one hour and 54 minutes, after labor of 15 hours. The predelivery medication of the mother had consisted of 250 mg. of meperidine and 150 mg. of promethazine. In the third case, the infant was delivered by cesarean section of a mother who had shown symptoms of preeclamptic toxemia. This patient had received 3 grains (0.19 Gm.) of phenobarbital (Luminal) sodium and ¼ grain (15 mg.) of morphine, in addition to 50 mg. of promethazine in the preanesthetic medication. The fourth infant, delivered spontaneously after 12 hours and 50 minutes' labor, showed evidence of asphyxia as a result of a tight nuchal cord. The mother had received 200 mg. of meperidine and 75 mg. of promethazine for predelivery analgesia and sedation.

Nine of the 262 viable infants had either congenital malformations (six infants) or symptoms suggesting brain damage (three infants, or 1% of the series).

The infants exhibiting signs of neurological damage included one male in whom cerebral palsy was probable (he had been delivered of a primipara, with low forceps, under peridural anesthesia of two hours' duration after 20 hours of labor), one male with symptoms of meningism (delivered of a multipara, with low forceps, under general anesthesia for 30 minutes after about 15 hours' labor), one female with symptoms of cerebral irritation (delivered of a primipara, with low forceps, under peridural anesthesia for 45 minutes after 20 hours of labor, and with a tight nuchal cord).

Postpartum Period.—Vomiting occurred in four patients after delivery and was controlled in each case by an additional injection of 25 mg. of pro-

methazine. Two patients experienced postpartum hemorrhage, one on the 1st and one on the 10th day. Dehiscence of the episiotomy occurred in one patient. One had endometritis, a second pyelonephritis, and a third cystitis. Three complained of pain in the back and coccyx and one of headache (a multipara delivered under general anesthesia). Enlargement of the spleen was observed in one patient; monilial infection of the episiotomy developed in another; and a third had hemorrhoids.

Complications developed in six infants during the postpartum period; infection of the umbilical stump, thrush of the mouth, and impetigo on the face occurred in each of three infants. Purulent conjunctivitis occurred in two infants. A toxic erythema developed in one who had received a narcotic antagonist. No bacteria were found in cultures of nose and throat.

Ninety-nine per cent of the infants were discharged in good general condition. Of the remainder, the condition of two was considered "fair" (one infant had a congenital heart lesion and one showed symptoms of meningism). One infant with esophagotracheal fistula was transferred to another service for further evaluation.

Comment

The findings in this survey confirm the impressions obtained in our controlled initial study. We believe the best effect may be achieved by administering 50 to 75 mg. of promethazine intramuscularly early in labor before analgesia is needed. The sedation provided by one dose lasts four to five hours; the dose may be repeated as indicated. As distress becomes more severe, meperidine may be injected intramuscularly in doses of 50 mg.

Before the potentialities of promethazine in the obstetric field were realized, meperidine was used, we feel, in doses larger than were necessary to control the actual pain. Such doses were administered mainly because the parturient was excited and frightened and her appreciation of the contractions was exaggerated. On administration of promethazine early in the first stage, however, the patient is relaxed and relieved of her fears, so that effective labor is soon established, especially in the primipara. She sleeps or rests between pains throughout the course but remains mentally clear; thus, her own estimate of the need of analgesia becomes more reliable.

The atmosphere of the labor room is noticeably quieter; it is rare to hear a patient cry out even at the peak of the contractions. One of us (R. S. M.) thought, on first acquaintance with the labor room here after arrival from Britain, that the patients were "abnormally" quiet. He was surprised to find that the average total dose of meperidine required per patient was quite small. An obstetrician recently returned from New York was similarly impressed and believed the patients were under the influence of heavy doses of sedatives.

The patient arrives in the delivery room in a comparatively unfatigued state and, hence, is better able to cooperate with the anesthetist and obstetrician; she does not resist the anesthetic and under light nitrous oxide anesthesia is able to push effectively with her contractions.

Our experience, in common with that of other workers,[3] suggests that promethazine potentiates all anesthetic agents. Therefore, rapid induction of deeper anesthesia for delivery of the head is accomplished with smaller dosage. Patients are usually awake or can be aroused soon after delivery and repair, although they generally remain drowsy for several hours post partum.

The degree of relief provided by promethazine-meperidine medication is difficult to assess from the patients' statements after delivery. It may be impossible to obtain from multiparas reliable information for a valid comparison with previous obstetric experiences without asking leading questions. However, a multipara will usually state that the contractions were less distressing and that she was better able to relax and sleep in the intervals between pains than in previous labors managed with conventional medication.

The suppressive action of promethazine on the alerting response to pain, as demonstrated in animals, may explain the obvious relaxation produced in the parturient. This is apparently reflected in the shortening of labor[4] (particularly significant in primiparas) and in the definite reduction of the total amount of narcotics required. In our continued experience of two and one-half years with this regimen, we have gradually increased the average total dose of promethazine per patient and have steadily reduced the total amount of meperidine (table 5).

The antihistaminic, antiemetic,[5] antiedema,[6] and atropine-like[7] properties of the compound, as observed by others, have been clinically demonstrated in these patients. No evidences of sensitivity to the medication have developed. Our obstetricians have the impression that the antihistaminic action of the compound is reflected in lessened edema of the tissues traumatized by episiotomy or laceration and in more rapid healing after the repair. The drying action is such that atropine is no longer administered even before anesthetization with cyclopropane, and the strong antiemetic effects have rendered vomiting an extremely unusual experience even during and after use of anesthetic agents that predispose to emesis. A sedative is especially valuable when it reduces the incidence of vomiting and, consequently, the catastrophe of aspiration.

Unlike chlorpromazine and some other ataraxics, promethazine does not alter the maternal blood pressure or pulse rate or unfavorably influence the fetal heart rate. Thus, patients in shock, from whatever cause, are relieved of the additional insult of drug-induced hypotension. Similarly, fetuses in distress are not embarrassed further by a maternal blood pressure too low to provide adequate transport of oxygen across the placenta.

Promethazine is unaffected by narcotic antagonists. Should the mother have been given narcotics to the extent that either her or her baby's respiratory center is depressed, the antagonists are as effective as if the narcotics had been given alone. The drug is not in itself an analgesic; therefore, when pain is present, the administration of a narcotic or other analgesic is indicated. It has been our experience in these 7,500 obstetric cases and in over 15,000 surgical cases of all types and in all age groups that there are practically no contraindications to the use of promethazine. In a few elderly arteriosclerotic patients, intramuscular injection of over 75 mg. has given rise to a state of confusion and restlessness. This condition has been controlled easily by small doses of meperidine.

Promethazine is not a panacea for all the problems of obstetrics. It is an effective tranquilizer and, as such, renders labor less unpleasant and reduces the need for those analgesics and anesthetics which have undesirable side-actions. It is a safe drug with no undesirable side-effects, and its administration does not interfere with or preclude the use of any other drugs which the physician might wish to use.

Condition of Fetus.—Recent chemical studies[8] of fetal cord and maternal venous blood samples seem to indicate that promethazine either does not enter the placental circulation or does so slowly and in insignificant amounts. However, whether the compound crosses the placental barrier or not appears clinically unimportant, because it obviously has little or no adverse effect on the fetus.

The fetal respiratory centers are evidently benefited by the significant reduction in the dosage of depressant agents required for analgesia and anesthesia in the mother.[9] Spontaneous respiration in the newborn infant is the rule. Resuscitation is almost never required, except when some abnormality of delivery is involved or the infant has been asphyxiated by the winding of the cord about the neck or body. The use of narcotic antagonists has been almost eliminated. On delivery to the nursery, the infants are usually pink, crying lustily, and showing good muscle tone—a circumstance which impresses both pediatricians and nursing staff.

Fetal and Neonatal Mortality.—Analysis of the records covering the period from 1953 through 1957 (i. e., two and one-half years before and two and one-half years after the introduction of promethazine into predelivery medication) shows, first, no significant alteration in the incidence of full-term antepartum and intrapartum deaths. Aside from those caused by congenital anomalies and Rh incompatibility, the majority were (or are assumed to have been) the result of faults in the placenta or cord (table 1). Analysis shows, second, no pronounced difference in the incidence of full-term neonatal deaths (tables 1 and 2). Again, most of these deaths are the result of Rh incompatibility and congenital anomalies. Although the number of deaths from respiratory causes does not show a marked change during the period under review, the over-all incidence of respiratory complications has declined.

Morbidity.—Morbidity in the newborn infant from pulmonary complications, especially atelectasis and pneumonia, showed a significant decrease in the first two and one-half years that promethazine was used.

Since resuscitation of the newborn infant is now so infrequent, drug-induced respiratory depression apparently has been reduced to a satisfactory low level. We feel that, if this is so, neonatal respiratory depression from predelivery medication of the mother is now less important as a cause of neonatal death and morbidity than difficult delivery. However, the fact remains that in premature and complicated labors even small doses of respiratory depressants may be sufficient to upset the delicate balance governing survival.

Summary

The charts for more than 7,500 obstetric patients to whom promethazine and meperidine were administered for predelivery sedation-analgesia were reviewed. These were compared with the records covering the two and one-half years prior to the use of promethazine in obstetrics. Records for 263 consecutive, unselected patients delivered in 1957 were reviewed in detail. Forty-six per cent were primiparas. Labor was premature in 3%.

The average total dose of promethazine per patient has been gradually increased and the total amount of meperidine used consistently reduced. The total dose of promethazine averaged 56.5 mg. and of meperidine 93.7 mg. per patient, including those in whom labor was attended by abnormalities. The results with the promethazine-meperidine combination were as predictable as those from almost twice the amount of meperidine used alone; maternal analgesia and relaxation were vastly superior, and infant morbidity was decreased.

In 92%, labor and delivery were without complication or special difficulties. In 5%, labor was protracted and difficult, necessitating midpelvic forceps rotation and delivery. Cesarean section was performed in 3%. In none of these complicated cases was medication a contributing factor. The fetal mortality was 1%, and there were no neonatal deaths.

The analgesia of anesthetics and analgesics is potentiated by promethazine without any alteration of their action on the respiratory center; therefore, smaller doses are effective but less depressing. Atropine is no longer used before induction. Vomiting is rare, even with use of anesthetics that predispose to emesis.

The medication does not alter the vital signs in the mother or affect the fetal heart rate. This is of benefit to patients in shock and to infants who already have hypoxia.

Ninety-five per cent of the viable infants cried spontaneously within one minute of delivery. Resuscitation is almost never necessary, and the use of narcotic antagonists has been almost eliminated.

There has been little or no change in the incidence of full-term antepartum, intrapartum, and neonatal deaths. Morbidity in the newborn infant from pulmonary complications has been reduced. The shortening of labor is particularly significant in uncomplicated primiparous cases.

The combination of meperidine and promethazine for patients in labor is recommended, since this regimen provides superior sedation-analgesia and is attended by greater safety than is use of meperidine alone.

1530 W. 37th Ave. (Dr. Carroll).

The promethazine hydrochloride used in this study was supplied as Phenergan hydrochloride by Poulenc, Ltd., Montreal, Canada.

CAUSES VERSUS SYMPTOMS IN AUTOMOBILE ACCIDENTS

Robert C. Blossom, Sacramento, Calif.

Recently, a member of the American Medical Association forwarded to the Department of California Highway Patrol a request that a representative of this department present a paper before the Committee on Medical Aspects of Automobile Injuries and Deaths. The context of the paper was to be "Causes of Automobile Accidents." This request seemed appropriate, as the California Highway Patrol presently employs approximately 2,000 officers who are well trained in accident investigation and, during the past 30 years, has carefully analyzed investigation reports covering more than 2 million automobile accidents.

Data secured from these reports are coded, tabulated, and exposed to the mathematical scrutiny of an electronic computer capable of calculating

Basic causes of automobile accidents cannot be classified in such terms as speeding, wrong side of the road, or drunken driving. True causes must be listed in such terms as anxiety, causing preoccupation; heart attack, resulting in loss of consciousness; or prolonged use of alcohol, resulting in psychotic condition. The most effective method of treating the problem of automobile deaths and injuries is the attacking of the basic causes, thereby effecting a reduction in the number of accidents. The most effective approach to accident prevention is through active, planned use of methods available only to the medical profession.

Research and Development Officer, California Highway Patrol.

Read in the Symposium and Panel Discussion on Motor Vehicle Accidents and Their Prevention in the Session on Traffic Accidents before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

mathematical correlations at the rate of 200,000 per minute. The finished analytic summaries are transmitted to the research and development officer for his review prior to dissemination.

Certainly, the research and development officer should have a wealth of information regarding the causes of traffic accidents. However, when the request from the A. M. A. was referred to me, I was forced to reply that the factual data regarding accident causes were almost nonexistent. This statement appeared so unreasonable that I was asked to appear before the Committee and explain it. The basis for the statement was as follows.

The Search for Basic Causes

For 30 years those agencies responsible for dealing with the social illness called traffic accidents have adopted almost the same method as the medical field dealing with the common cold. In other words, they have constantly explored methods of treatment of the symptoms of the illness and have realized almost no progress in attempts to analyze basic causes.

This fact will become self-evident if one considers such subjects as types and degrees of injuries, chemical tests to determine intoxication, and effect of seat belts. Each discussion may provide assistance to accident prevention agencies but will not further the search for facts regarding basic causes. The reason for this is that basic causes cannot be classified in such terms as speeding, wrong side of the road, or drunken driving. True causes must be listed in such terms as anxiety, causing preoccupation; heart attack, resulting in loss of consciousness; or prolonged use of alcohol, resulting in psychotic condition.

The validity of this conclusion is borne out by a recent analysis of coroners' reports covering motor vehicle deaths submitted to this department. In 653 reports submitted by an agency that had access to adequate postmortem examination, 30 of the reported deaths received preliminary listing as "may have been due to natural causes." Later, autopsies increased this figure to 62. The inability to determine whether physiological conditions caused the accident or the accident aggravated the existing condition may have restricted additions to this figure.

From this small sample, plus logic, it would appear that existing and induced physiological conditions of drivers involved in fatal automobile accidents may constitute a major portion of the true causes of death in an automobile. Our logic may be based on scrutiny of the actual time spent in automobiles. A total of 1.5 billion hours—200 hours per driver per year or approximately 3% of total time of each driver—is spent in an automobile in California. If 3% of the natural deaths due to chronic disease should occur during this time span, the number would approximate 1,350 deaths. This argument, while logical, will not allow a conclusion, because there are factors which have not been evaluated. However, the sample, plus logic, does indicate that it is necessary to attempt to lessen the influence of physiological conditions of drivers in automobile deaths.

Responsibility of the Medical Profession

It is my opinion that the most effective approach to this is through active, planned use of methods available only to the medical profession. It is also my opinion that the medical profession is presently unaware of the significance of this aspect of the problem and consequently is not taking active or planned curative action.

For example: how many doctors, when diagnosing hypertension, recommend relaxation through an automobile trip down crowded highways? How many depressant or stimulating drugs are administered without restriction being placed on the patient's driving? How many patients with cardiac problems are cautioned about the strain involved in driving at high speeds on crowded freeways? How many persons suffering from diabetes are, because of sugar imbalance, exposing other motorists and themselves to destruction?

Another small sampling was recently conducted which may lead to an inference in this regard. One hundred convicted drunken drivers were asked if they had discussed with a physician their problem of drinking and driving. Out of the 100, only 7 had discussed with a doctor their excessive drinking and, in these 7 instances, the problem of their drinking as it affected their driving was not mentioned.

Conclusions

The preceding information results in the following conclusions: The most effective method of treatment of the problem of automobile deaths and injuries is attacking the basic causes, thereby effecting a reduction in the number of accidents. Basic causes are existing mental and physiological conditions of drivers which dictate such behavior as speeding or reckless driving. Planned action cannot be effectively taken unless facts are gathered by joint research teams composed of representatives of the medical profession and existing accident-prevention agencies. Unless these steps are taken, 10 years from today we will have investigated and analyzed 15 million more accidents and still be forced to admit that we know very little about the basic causes of those accidents.

INFLUENCE OF CHLOROTHIAZIDE ON WATER AND ELECTROLYTE EXCRETION IN PREECLAMPSIA

Russell R. de Alvarez, M.D.
and
John M. O'Lane, M.D., Seattle

The mechanism of the diuresis provoked by chlorothiazide was studied in 14 women hospitalized for toxemia of pregnancy. They received 500 mg. of chlorothiazide orally twice a day in addition to a well-established basic treatment for toxemia, and the results were compared with those in a group of 23 patients who received the basic treatment without the chlorothiazide. It was also possible to compare two-day periods in which the drug was given with two-day periods in which it was withheld. While the drug did not cause any consistent changes in the urinary pH, titratable acidity, mean urinary ammonia level, serum carbon dioxide content, serum sodium level, serum potassium level, serum chloride level, or patient's body weight, it did cause a marked increase in the urinary excretion of sodium, potassium, and chloride. Chlorothiazide in vitro strongly inhibits carbonic anhydrase, but its action under the conditions described in patients with preeclampsia differed from that of other carbonic anhydrase-inhibiting diuretics and also from that of mercurial diuretics.

It has long been a goal of research scientists to develop a diuretic drug which would be effective on oral administration and which would not produce serious electrolyte imbalance. Recently, chlorothiazide (Diuril), a new diuretic agent, has shown considerable promise in animal experiments. Chemically, chlorothiazide is 6-chloro-7-sulfamyl-1, 2, 4-benzothiadiazine-1, 1-dioxide.[1] Its structure is represented in figure 1. This compound is structurally related to some carbonic anhydrase-inhibiting diuretics, in that it contains a sulfamyl group attached to a benzene ring.

Preclinical experiments indicate that this compound possesses a high degree of activity as an inhibitor of carbonic anhydrase in vitro.[2] It is considered to be about 10 to 30 times as potent as sulfanilamide in this respect. In animals, chlorothiazide causes a marked increase in the urinary excretion of sodium, potassium, chloride, and water.[3] Excreted sodium is matched approximately mol for mol by chloride ions.[2] This effect is similar to that of mercurial diuretics, although chlorothiazide does not contain mercury. At high doses, bicarbonate excretion takes place, presumably because of inhibition of carbonic anhydrase. Because chlorothiazide is an effective diuretic in dogs at doses which do not produce bicarbonate excretion, these animal experiments suggest that its mechanism of action cannot be explained on the basis of carbonic anhydrase inhibition. Since the mechanism of this agent is still doubtful, we were particularly interested to investigate both the clinical effectiveness and the mechanism of action of chlorothiazide in some of the abnormalities of human pregnancy.

Materials and Methods

All patients diagnosed as having toxemia of pregnancy who were admitted to the obstetrics and gynecology service of King County Hospital during a period limited to the study of chlorothiazide were included in this study, with the exception of those patients who left the hospital against medical advice before the experimental period had elapsed. All patients were hospitalized during the period of investigation. The final diagnosis of toxemia was based on information obtained during the antepartum period, the period of hospitalization, and the follow-up period, at least three months post partum. The series consisted of a total of 14 women, 9 Caucasian, 3 Negro, and 2 American Indian, who were investigated during the immediate postpartum period in the hospital. This group of patients lent itself to comparison with another group of similar patients with toxemia of pregnancy previously studied in the same manner, with the exception that no diuretic drug was administered. In this controlled study of hospitalized patients we were able to investigate extensively many factors bearing on the course of toxemia of pregnancy and to analyze the effect of chlorothiazide in modifying those factors.

Each patient was studied over a seven-day period. Bed rest was enforced for the first three days, after which the majority of patients were made ambulant. A food intake consisting of a 1,200-calorie, neutral-ash, low-salt diet, containing approximately 30 mEq. of sodium daily, was maintained unless the patient was unable to tolerate oral feedings, in which case intravenous feedings were

---

From the Department of Obstetrics and Gynecology, University of Washington School of Medicine and Hospitals.

carried out. Food trays were weighed before and after each meal, and the actual daily intake of sodium, calories, acid, and basic ash was calculated. Sedation in varying degrees depending on the severity of the toxemia was prescribed as appropriate. All urine was collected as 24-hour specimens and kept under 25 ml. of mineral oil in order to prevent alterations in chemical values because of exposure to air. To prevent contamination by lochia, the urine from all postpartum patients was collected through indwelling Foley catheters.

The foregoing general measures constitute the general toxemia regimen of the department of obstetrics and gynecology of the University of Washington and have been kept constant for several years. The only modification from the usual program was the addition of 500 mg. of chlorothiazide given orally twice a day in the experimental group. Patients in the control group received no diuretic agents. During the first 24 hours of hospitalization no chlorothiazide was administered. On the second and third postpartum days, 500 mg. of chlorothiazide was given twice daily. During the fourth and fifth postpartum days, no chlorothiazide was given. On the sixth and seventh days the drug was again administered in the same dosage.

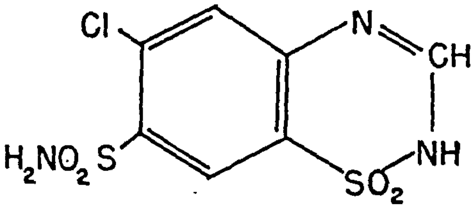

Fig. 1.—Chemical structure of chlorothiazide.

Serum sodium, potassium, and chloride levels were determined daily. On the second, fourth, and sixth hospital days blood urea nitrogen level, total protein level, albumin-globulin ratio, and fibrinogen and serum carbon dioxide levels were measured. On each of the daily 24-hour urine samples, urine pH, total volume, albumin level, specific gravity, ammonia content, titratable acidity, and sodium, potassium, and chloride levels were determined. The weight of each patient in grams was determined daily at the same time by the same person on a specially constructed scale for bedside weighing. The weights were accurate to 10 Gm. Blood pressure and edema were evaluated daily by the same person.

Sodium and potassium levels were determined by a flame photometer method with use of the Baird spectrophotometer. The chloride level was determined by the method of Schales and Schales,[4] blood urea nitrogen level by a slight modification of the method of Van Slyke and Cope,[5] carbon dioxide content by a slight modification of the method of Van Slyke and Neill,[6] titratable acidity by the method outlined by Hawk and co-workers,[7] ammonia by a slight modification of the method of Van Slyke and Cullen,[8] and pH with the Beckman, model G, pH meter.

All data were submitted to statistical analysis to determine the effect of chlorothiazide on the course of toxemia of pregnancy in the postpartum period. Since most reports attach great significance to the day-to-day changes occurring after the administration of a given drug, we considered it highly important to determine whether such changes would occur in a group of patients similarly treated except for the use of the drug. The fact that untreated patients may exhibit statistically significant changes from day to day makes it imperative that observations be made in a control group if the effect of a drug is to be properly evaluated. It is incorrect to ascribe to the action of a drug the finding of a significant difference until control studies have been performed. The failure to observe this principle has led to much confusion and misinformation in the past.

The Student's *t* test[9] was used to compare means in the chlorothiazide and control groups on a day-for-day basis. The reproducibility of the individual determinations was considered in establishing the p values on levels thought to be significant. In general, those observations having a low coefficient of variation, such as on the serum electrolytes, were considered significant at a level of $p=0.01$. For observations having a high coefficient of variation, as on the urine electrolytes and weight gain, the level of significance was established at $p=0.05$.

Results

The results obtained in this study in the 14 postpartum patients with toxemia of pregnancy who were treated with chlorothiazide are summarized in table 1. The results obtained in the group of 23 patients with toxemia of pregnancy studied in the postpartum period who did not receive any diuretic drugs are summarized in table 2. The latter group will be referred to as the control group.

Urine Sodium.—As shown in table 1, the urine sodium excretion remained constant during the first three days, being 73.2 mEq. per 24 hours the first (no drug) day and 70.7 and 75.9 on the second and third postpartum days, which were the first two days that the drug was given. Thus, the patients treated with chlorothiazide did not experience the drop in sodium excretion that the control group did (fig. 2). Significant increases of sodium excretion were found on the second day of the first course of drug administration (control group 47.3 mEq. per 24 hours, chlorothiazide group 75.9 mEq. per 24 hours: $p=0.05$) and on both days of the second course (control group 23.6 mEq. per 24 hours, chlorothiazide group 59.7 mEq. per 24 hours: $p=$

0.002; control group 28.0 mEq. per 24 hours, chlorothiazide group 66.2 mEq. per 24 hours: p=0.005). On the fourth and fifth days, on which no drug was given, the chlorothiazide group excreted significantly less sodium than the control group (control group 59.1 mEq. per 24 hours, chlorothiazide group 31.6 mEq. per 24 hours: p=0.04; control group 42.6 mEq. per 24 hours, chlorothiazide group 28.9 mEq. per 24 hours: p=0.05). The level of significance for this determination was established at p=0.05.

† Chlorothiazide, 1,000 mg.
‡ Determined prior to drug administration.

Urine Potassium.—In the chlorothiazide group the urine potassium excretion increased during the administration of chlorothiazide and decreased when the drug was withdrawn. In general, the changes were more pronounced quantitatively than those of urine sodium excretion. When the chlorothiazide group was compared to the control group it was found that, in contrast to findings on urine sodium, a statistically significant increase in excretion of urinary potassium occurred on each day of both the first drug period (control group 56.2 mEq. per 24 hours, chlorothiazide group 89.3 mEq. per 24 hours: p=0.004; control group 50.0 mEq. per 24 hours, chlorothiazide group 92.8 mEq. per 24 hours: p=<0.001) and the second drug period (control group 54.5 mEq. per 24 hours, chlorothiazide group 81.9 mEq. per 24 hours: p=0.005; control group 45.9 mEq. per 24 hours, chlorothiazide group 90.4 mEq. per 24 hours: p=0.001), as illustrated in figure 3. The statistical level of significance for this determination was established at p=0.05.

* No.=number of patients; S.D.=standard deviation.

Urine Chloride.—Mean urine chloride excretion rose sharply from that of the control group during the first course of chlorothiazide therapy, as shown in figure 4 (first drug day: control group 77.4 mEq. per 24 hours, chlorothiazide group 129.1 mEq. per 24 hours: p=0.007, second drug day: control group 51.0 mEq. per 24 hours, chlorothiazide group 107.4 mEq. per 24 hours: p=<0.001). The chloride excretion rose from 52.9 mEq. per 24 hours on the first (no drug) day to 129.1 mEq. per 24 hours on the first day of drug administration. As was also noted for the urine sodium excretion, the excretion rate of chloride fell below the control values on the rest days (days four and five) after the first course of chlorothiazide therapy. This decrease was statistically significant on the fifth day (fourth day: control group 50.5 mEq. per 24 hours, chlorothiazide group 33.3 mEq. per 24 hours: p=0.10; fifth day: control group 47.7 mEq. per 24 hours, chlorothiazide group 25.1 mEq. per 24 hours: p=0.005).

During the second course of chlorothiazide therapy the chloride excretion rate was markedly reduced and was significantly increased from that of the control group only on the second, or seventh postpartum, day (control 35.8 mEq. per 24 hours, chlorothiazide group 59.2 mEq. per 24 hours: p=0.02). The statistical level of significance for this determination was established at p=0.05.

Urine pH.—The urine pH showed no consistent pattern of change. The lowest mean value was 6.11 and the highest 6.40. No significant changes from day to day in mean pH were detected. In fact, on each day certain patients' urine pH went up slightly while that of other patients went down slightly. The level of significance for this determination was set at p=0.01.

Titratable Acidity.—Urinary titratable acidity varied from 27.7 mEq. per 24 hours to 30.3 mEq. per 24 hours during the seven days of observation. With the level of significance set at p=0.01, no significant differences from day to day in mean titratable acidity were noted. As in the pH determination, some patients had slight increases in titratable acidity and others slight decreases on the same day. No consistent pattern of titratable acidity change with drug administration could be made out.

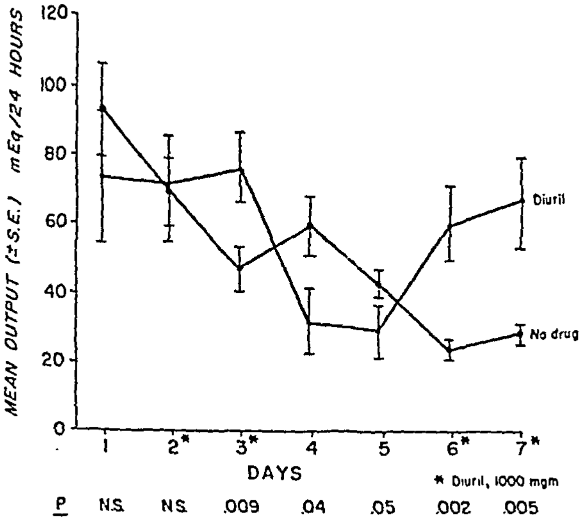

Fig. 2.—Increased urine sodium excretion in postpartum patients with toxemia of pregnancy treated with chlorothiazide over that of similar patients given no drug.

Urine Ammonia.—Mean urine ammonia level varied from 46.9 mEq. per 24 hours to 83.2 mEq. per 24 hours during the seven days of observation. With the level of significance set at p=0.01, no significant differences from day to day were noted. On the second day (first drug day) and the fifth day (second day of the rest period), increases in urine ammonia levels which might be labeled "almost significant" occurred (first drug day p=0.02; second rest day p=0.03). Since these increases in urine ammonia levels were observed both when the drug was given (second day) and when the drug was withheld (fifth day), it is difficult to attach much importance to this finding. On neither of these days was enough change seen to be considered statistically significant, and, therefore, we ascribe the changes on the first drug day and the second rest day to chance.

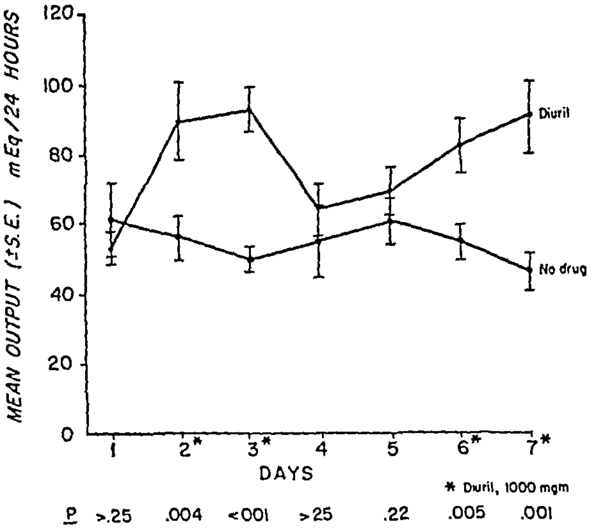

Fig. 3.—Increased potassium urine excretion in postpartum patients with toxemia of pregnancy treated with chlorothiazide over that of similar patients given no drug.

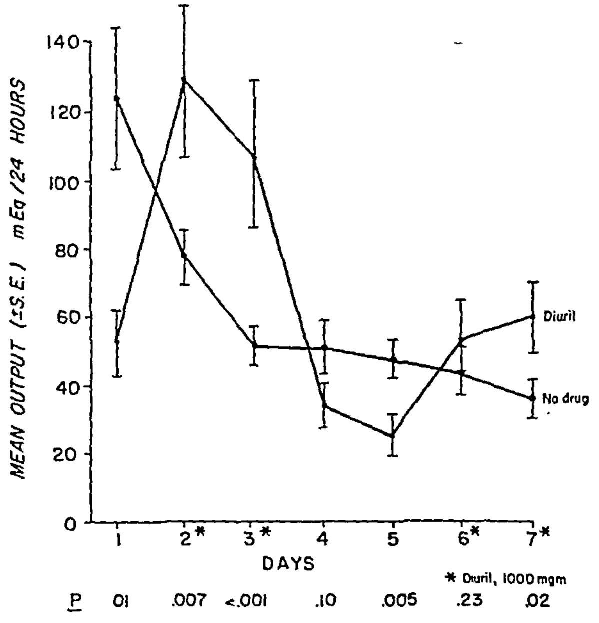

Fig. 4.—Increased urine chloride excretion, on three of four days that chlorothiazide was given, in postpartum patients with toxemia of pregnancy.

Serum Carbon Dioxide.—The serum carbon dioxide content did not change significantly from day to day during the administration of chlorothiazide.

Mean values were 23.1, 23.3, and 24.3 mEq. per liter respectively. The statistical level of significance for this determination was set at p=0.01.

Serum Sodium.—The mean serum sodium values for the chlorothiazide group and the control group are shown in figure 5. It is seen that on the second day of drug administration essentially no change in serum sodium levels occurred. The mean value for the chlorothiazide group was 135.5 mEq. per liter on the first drug day, changing to 135.3 mEq. per liter on the second drug day (the third day of observation). The control group, however, experienced an increase on the corresponding day from 137.7 to 141.2 mEq. per liter. The change in serum sodium levels exhibited by the control group constituted a significant difference, compared to the change exhibited by the chlorothiazide group (p=0.001). Thus, on the second day of drug administration the serum sodium levels in the drug group were not seen to have the same increase as in the control group. Similarly, on the second day of administration of chlorothiazide in the second course of therapy the chlorothiazide group did not show a corresponding elevation of serum sodium levels when compared with the control group (control 142.6 mEq. per liter, chlorothiazide group 136.2 mEq. per liter: p=0.001).

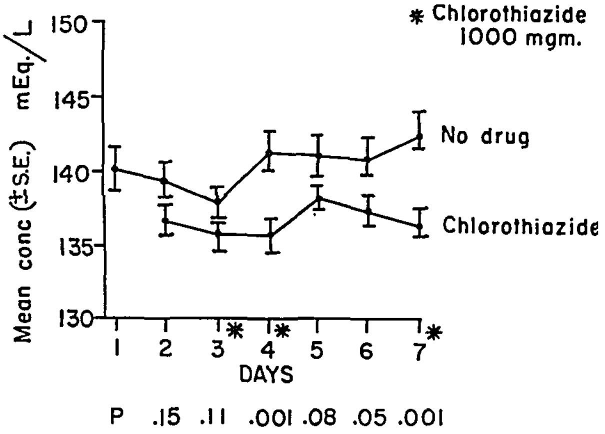

Fig. 5.—Serum sodium levels in postpartum patients with toxemia of pregnancy. Since blood specimens were obtained on days two and six before drug was administered, effect of chlorothiazide on serum sodium is reflected in values for days three, four, and seven. Note that mean serum sodium level of chlorothiazide group was not elevated on days four and seven.

Serum Potassium.—The mean serum potassium level varied from a low of 4.38 to a high of 4.75 mEq. per liter during the seven-day period of observation. No statistically significant variation in the serum potassium level was detected through the course of this study. The statistical level of significance for this determination was set at p=0.01.

Serum Chloride.—The serum chloride level varied from a low of 97.4 mEq. per liter to a high of 101.1 mEq. per liter. The statistical level of significance for this determination was set at p=0.01. No significant changes in the level of serum chloride were found.

Patients' Weight.—Weight changes of the chlorothiazide patients were not impressive when compared with those of the control group (fig. 6). The only day in which the drug group lost significantly more weight than the control group was on the second drug day (control 0.55 kg. [1⅛ lb.], chlorothiazide group 1.25 kg. [3 lb.]: p=0.04). On the following day (the first rest day) the control group lost significantly more than the drug group (control 0.59 [1⅙ lb.], chlorothiazide group 0.08 kg. [⅙ lb.]: p=0.025). While the average for all patients in the drug group was a net loss in weight each day, there actually were several cases in which patients gained weight while receiving chlorothiazide.

Toxicity.—In one patient who had bleeding during the third trimester, administration of the initial dose of chlorothiazide was followed by shock with increased pulse rate, decreased blood pressure, and pronounced diaphoresis. After blood transfusion, the patient improved; on subsequent delivery a partial abruption of the placenta was demonstrated. It is believed that her symptoms of shock could be considered as secondary to the abruption of the placenta and not secondary to the administration of chlorothiazide. No definitely related instances of toxicity of any sort were noted during the course of the study.

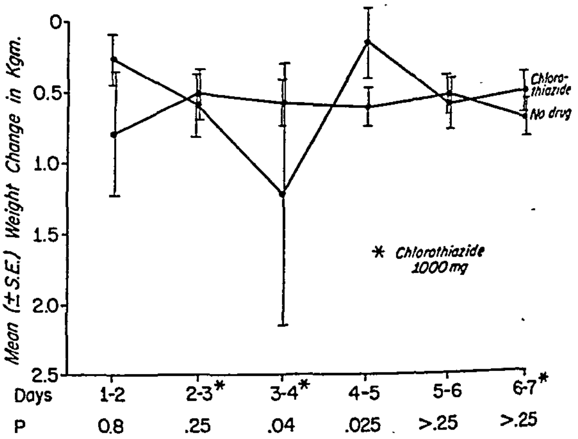

Fig. 6.—Weight change in chlorothiazide and control groups, showing loss of approximately same amount of weight during period of investigation.

Comment

Chlorothiazide, when administered in the postpartum period to patients with toxemia of pregnancy in doses of 500 mg. twice a day, produced the following effects:

The urinary excretion of sodium, potassium, and chloride was markedly increased. Urine pH, titratable acidity, and ammonia levels were not changed significantly.

Serum chloride, potassium, and carbon dioxide levels were not significantly altered. The serum sodium level of these patients failed to show the control pattern of increase when chlorothiazide was given.

It is interesting that the chlorothiazide group excreted significantly less sodium in the urine than the control group during the fourth and fifth days of the study, on which no chlorothiazide was given. While one might have expected the urine sodium level to drop to the control level when chlorothiazide therapy was discontinued, it does seem surprising that the level of sodium excretion should actually drop below that of the control group. The mechanism of such a change is not clear, especially in view of the finding that the serum sodium level was not altered significantly during this period. One might postulate that, since the drug group lost more sodium early in the experimental period because of the administration of chlorothiazide, an increased reabsorption of sodium occurred when the drug was withdrawn. The exact mechanism through which this increased reabsorption was accomplished remains to be determined. If chlorothiazide acts by blocking a normal renal mechanism for sodium reabsorption, the withdrawal of the drug could permit the "unblocking" of that mechanism with a subsequent decrease in urine sodium excretion. When the experimental group was compared with the control group, the urine potassium level was significantly increased during each day of drug administration.

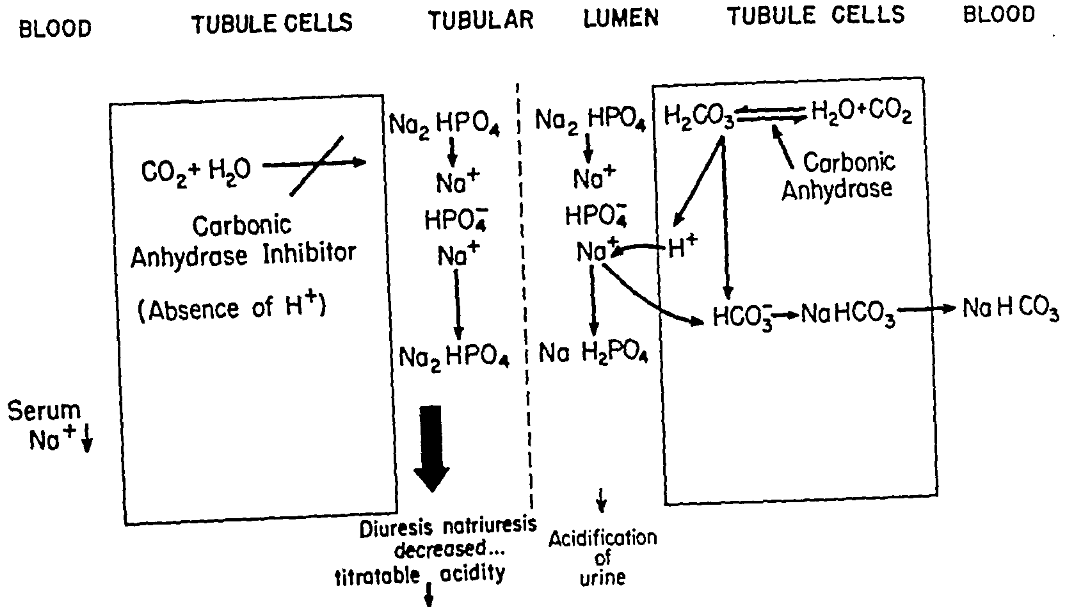

Fig. 7.—How inhibition of carbonic anhydrase decreases urine acidification.

It now seems well established that almost all of the potassium found in the urine results from an exchange with sodium in the distal convoluted tubule. Apparently that potassium which is filtered through the glomerulus is almost entirely reabsorbed in the proximal tubule. It follows, therefore, that any process which increases the sodium concentration in the distal tubule will enhance the excretion of potassium. In the distal tubule, both potassium and hydrogen ions within the tubule cell are exchanged for tubular sodium. Therefore, a process reducing the available hydrogen ion within the tubule cell would enhance potassium excretion, as occurs with carbonic anhydrase inhibitors. One can see that potassium excretion is affected by several varying processes; therefore, it is difficult to draw conclusions as to possible mechanisms of drug action from changes in the level of urine potassium.

The acidification of urine is dependent on the enzyme carbonic anhydrase. Its mechanism of action may be depicted as follows: In the renal tubule cells carbon dioxide from internal metabolism is combined with water to form carbonic acid which dissociates into hydrogen ions and bicarbonate ions. The hydrogen ions then pass across the cell membrane into the lumen of the tubule where they replace basic ions (for example, sodium) in the urine. This mechanism results in a conservation of the fixed basic ions of the body and in their replacement by hydrogen ions in the urine (fig. 7).

The urine pH may be considered as a measure of carbonic anhydrase activity in the kidney. As urinary acidification occurs, the pH of the urine should decrease. Therefore, a carbonic anhydrase inhibitor should cause an increase in the urine pH, because it reduces urinary acidification by blocking the formation of carbonic acid from carbon dioxide in the tubule cell. In animal experiments[10] no instance of the pH rising above 7.0 was observed when single doses of chlorothiazide were given. It has been reported[11] that large doses of chlorothiazide in man cause an increase in urinary pH but as dosage is reduced the urine becomes more acid, because the chloruretic effect persists in the face of a decreased bicarbonate excreting power. In some of our patients, the urine was alkaline. However, no statistically significant change in urine pH was demonstrated. This is an indication that, in the clinically effective doses used in this study, no measurable carbonic anhydrase inhibitory activity is detectable.

If chlorothiazide is an effective inhibitor of carbonic anhydrase activity, one would expect the titratable acidity to fall during the administration of the drug and to rise after its withdrawal, as is observed with classic carbonic anhydrase inhibitors. No such change was detected, indicating that carbonic anhydrase inhibition did not occur in our patients.

The measurement of urine ammonia level provides another indication of carbonic anhydrase activity. Glutamine is acted on in the renal tubule cell to give glutamic acid, plus ammonia, through the action of the enzyme glutaminase. The ammonia combines with hydrogen ions from the carbonic acid reaction to produce ammonium ions, which diffuse into the urine and replace basic cations (fig. 8).Of course, the urine ammonia determination may not be considered as specific a test for carbonic anhydrase function as those for pH and titratable acidity because, in addition to depending on available hydrogen ions, the urine ammonia level also depends on a functioning glutaminase and on urine pH. As the patient's nitrogen intake is held relatively constant, inhibition of carbonic anhydrase by chlorothiazide should be reflected by decreased urine ammonia levels during periods of drug administration. No such decrease was observed. The observation that there was no significant change in urine ammonia levels may be interpreted best as an indication that no dysfunction of either the glutaminase or carbonic anhydrase systems occurred as a result of chlorothiazide therapy. This agrees with and lends support to the finding that there is no significant change in titratable acidity and pH and is strong evidence that no inhibition of carbonic anhydrase activity occurred in our patients.

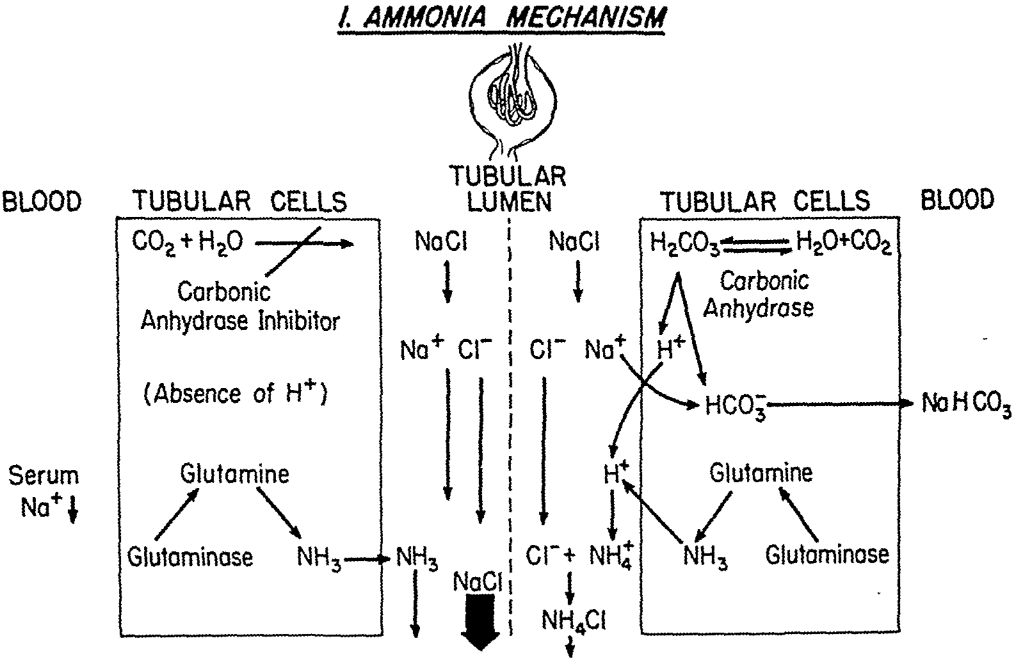

Fig. 8.—Interaction of carbonic anhydrase and glutaminase systems in reabsorption of urine sodium.

The carbon dioxide content did not change significantly during the administration of chlorothiazide. The classic carbonic anhydrase inhibitor type of diuretic produces a state of metabolic acidosis after a day or two of administration. This may be explained on the basis of the electrolyte excretion pattern. Thus, sodium, potassium, and bicarbonate are excreted in large amounts, while almost no hydrogen ion is excreted. This means that there is a net loss of basic cations (sodium and potassium) with the production of hyponatremic, hypokalemic, metabolic acidosis. The serum carbon dioxide level is, therefore, markedly reduced.

The fact that no significant reduction in serum carbon dioxide content was observed indicates that acidosis was not evident in our patients with the doses used in our study. This observation provides evidence that carbonic anhydrase inhibition does not explain the mechanism of action of chlorothiazide. Neither is this action similar to that of mercurial diuretics. These agents characteristically cause hypochloremic metabolic alkalosis with a compensatory increase in serum carbon dioxide level. In its effects on serum carbon dioxide, chlorothiazide differs from both of these groups of diuretics.

Some cardiac patients have been reported to exhibit signs and symptoms of low serum sodium levels after administration of chlorothiazide.[10] This was observed in one of our patients with chronic renal disease, diagnosed as diabetic glomerulosclerosis after renal biopsy. No other patient exhibited an unusually low serum sodium level.

Comparison of Chlorothiazide with Carbonic Anhydrase Inhibitors.—When compared with carbonic anhydrase inhibitors, chlorothiazide exhibits striking differences, as shown in figure 9. Carbonic anhydrase inhibitors characteristically produce an increase in urine pH and a decrease in urine titratable acidity and ammonia level. These changes were not observed during the administration of chlorothiazide. Chlorothiazide is similar to carbonic anhydrase inhibitors in that both agents produce increased urinary excretion of sodium and potassium. While carbonic anhydrase inhibitors cause little change in chloride excretion, chlorothiazide results in a markedly increased excretion of chloride. Carbonic anhydrase inhibitors tend to lower serum sodium and potassium levels. This did not occur in the chlorothiazide group. However, a rise in serum sodium level which occurred in our untreated, control patients did not occur in the chlorothiazide group. Finally, carbonic anhydrase inhibitors cause metabolic acidosis, as determined by low serum carbon dioxide content; in our hands chlorothiazide caused no acid-base imbalance, and the serum carbon dioxide content was not significantly changed. At the doses used the carbonic anhydrase inhibitory properties of chlorothiazide demonstrable in vitro were not observed in vivo.

Animal experiments reported by Ford and others[11] have indicated that the diuresis mechanism of chlorothiazide is different from that of the classic carbonic anhydrase inhibitor acetazolamide. Apparently, the carbonic anhydrase-inhibiting properties which are demonstrable in vitro are not responsible for the diuretic effect, for, unlike acetazolamide, chlorothiazide causes (in animals) the excretion of similar amounts of sodium and chloride. It does not result in acidosis and does not lose its effectiveness if given on successive days. In general, our results in women with toxemia of pregnancy confirm those found by Ford and Spurr in their animal experiments.

It is important to consider that the statements made about lack of carbonic anhydrase inhibition apply to the dosage schedule used in our study. Perhaps at a higher dosage level or with prolongation of administration carbonic anhydrase inhibition might manifest itself, causing a much different excretion of electrolytes.

Additional evidence for a different mechanism of action between chlorothiazide and carbonic anhydrase inhibitors is provided by the studies of Finnerty and associates[12] on patients with toxemia of pregnancy. Their results, based on weight losses without electrolyte studies in clinic outpatients, showed a potentiation of acetazolamide diuresis when chlorothiazide was administered. The foregoing evidence, both from the literature and from our own studies, seems to indicate conclusively that chlorothiazide acts through some mechanism other than inhibition of the enzyme carbonic anhydrase.

Fig. 9.—Action of chlorothiazide in toxemia of pregnancy contrasted with that of carbonic anhydrase inhibitors, mercurial diuretics, and chlorothiazide in nonpregnant patients.

Comparison of Chlorothiazide with Mercurial Diuretics.—The electrolyte excretion pattern of sodium and chloride is qualitatively similar with both chlorothiazide and mercurials (fig. 9). Chlorothiazide causes a marked excretion of potassium, which is not observed with mercurials. In the serum, mercurials tend to cause hypochloremia with associated metabolic alkalosis and elevated serum carbon dioxide level. These serum changes were not observed with chlorothiazide.

While the electrolyte excretion pattern of chlorothiazide in the moderate doses used for this study somewhat resembles that of mercurial diuretics, Laragh[13] has cited several reasons to indicate that a different mechanism is involved. The activity of chlorothiazide is neither inhibited nor reversed by dimercaprol. Conditions refractory to mercurials have responded to chlorothiazide, while those refractory to each drug given separately may respond to both drugs given simultaneously. The addition of a second drug for patients already receiving one agent often gives an increased diuresis. Steroid-induced edema is inhibited or reversed by chlorothiazide, while the mercurials are usually ineffective in such cases. Chlorothiazide is effective in hypochloremic alkalosis, while mercurials are not. The addition of ammonium chloride results in a potentiation of mercurial action, while chlorothiazide action is unaffected.

These facts, together with the differences in serum and urine electrolyte balances demonstrated in our study, provide good evidence that chlorothiazide has a different mechanism of action from mercurial diuretics.

Possible Mechanism of Chlorothiazide.—One explanation of the mechanism of chlorothiazide which accounts for the observations made in our study is that the drug in some way inhibits sodium reabsorption in the proximal renal tubule. This would result in the delivery of an increased amount of sodium into the distal renal tubule. The increased sodium level would provide more opportunity for potassium exchange in the distal tubule, leading to an increased excretion of potassium. Because not all of the extra sodium is replaced by potassium, the amount of sodium delivered into the urine would be increased also. Since it is believed that chloride ions follow sodium ions rather passively, with the blocking of sodium reabsorption in the proximal tubule, a larger amount of chloride would flow into the distal tubule. There is no known active mechanism affecting chloride ions in the distal tubule, and the increased amount of chloride is thought to pass into the urine in association with the increased sodium and potassium levels. Thus, increased excretion of sodium, potassium, and chloride could occur on the basis of a blocking of reabsorption of the single ion, sodium.

Conclusions

Chlorothiazide is a potent agent in promoting the excretion of sodium, potassium, and chloride from the body. When it was administered in a dosage of 500 mg. twice daily for two-day periods with a two-day rest period between each course of therapy, no serum electrolyte abnormalities were noted to occur. Despite the pronounced elevation of electrolyte excretion caused by chlorothiazide, patients with toxemia of pregnancy studied during the postpartum period did not lose weight at a significantly faster rate than patients not given the drug. Chlorothiazide is equally effective on readministration after a two-day rest period. No instances of toxicity or undesirable side-effects were noted.

This study was supported, in part, by a grant from the Pacific Northwest Obstetrical and Gynecological Society.

The chlorothiazide used in this study was supplied as Diuril through Dr. John R. Beem of Merck Sharp & Dohme, Division of Merck & Co., Inc., Philadelphia.

We wish to express our appreciation to Miss Gloria E. Bratvold, Research Associate, Miss Janice Ekholm and Miss Donna Simkins for technical assistance, and Miss Ruth Portman for assistance in statistical analysis.

PATHOLOGICAL FINDINGS IN JAUNDICE ASSOCIATED WITH IPRONIAZID THERAPY

Hans Popper, M.D., New York

Specimens of liver tissue were studied in 27 patients who had developed jaundice after taking iproniazid in amounts that totaled from 600 to 19,200 mg. over treatment periods ranging from 4 to 126 days. The aim was to define the type of hepatocellular damage associated with the jaundice and to account for the evident lack of relation between the dose of iproniazid and the severity of the hepatic lesions. The biopsy specimens showed severe spotty necrotic hepatitis with or without extensive necrosis: the 16 autopsy specimens showed either acute massive and submissive necrotic hepatitis or subacute hepatitis with massive and submassive collapse. Clinically, the findings were those of diffuse parenchymal liver disease, mostly without fever, commonly with hepatomegaly, and with terminal hepatic coma in the fatal cases. Results of conventional laboratory tests are tabulated. In some cases the jaundice appeared as late as 20 days after the cessation of therapy. Either the iproniazid activated existing subclinical viral hepatitis or else it was able to produce morphologic changes closely resembling those of viral hepatitis. In either case the possibility of inducing an insidious form of liver disease with high mortality should be kept in mind whenever the administration of iproniazid is found necessary.

The evaluation of injurious effects of drugs and chemicals on the liver is frequently difficult. Some of these, e. g., carbon tetrachloride, cause characteristic functional disturbances and structural alterations in the liver of all persons exposed to them. A close relationship between dose and extent of lesion exists, and the changes are reproducible in experimental animals. In contrast, some drugs produce hepatic injury only in some persons exposed to them—in fact, the percentage of those afflicted may be very small, the dose relation is not always evident, and the lesion cannot be produced in animals at will. In such instances, even if the hepatic injury is associated with jaundice, a causal relation between drug intake and liver damage has been recognized only after the observation of a considerable number of similar cases; the mechanism of this injury remains not established. Hepatic injuries of the cholestatic type, occurring after the administration of chlorpromazine, methyltestosterone, norethandrolone, or other drugs,[1] fall into this category.

Iproniazid (Marsilid) phosphate (1-isonicotinyl-2-isopropylhydrazine), an amine oxidase inhibitor initially used in the treatment of tuberculosis,[2] was recently found to be effective in alleviating various mental disorders, particularly depressions.[3] After the widespread use of iproniazid, reports of cases of jaundice have appeared [4] which developed after administration of this drug and may be related to it. The jaundice in iproniazid-treated patients is associated with biochemical evidence of significant hepatocellular injury and, in contrast to the cholestatic type of hepatic damage, the mortality is relatively high. To determine the type of injury and possible causal relation to drug intake, a study was made of the pathological features of biopsy and autopsy specimens of liver of patients who had developed jaundice after administration of iproniazid. An attempt was made to correlate these findings with the clinical manifestations of the hepatic disease and with the dosage of drug administered.

Material and Methods

The study comprised 13 biopsy specimens and 16 autopsy specimens obtained from 27 patients. Of the 23 patients on whom pertinent data are available, 16 were females and 7 males, and their ages ranged from 21 to 82 years. Ten patients were under 50 years of age; five patients each were in their sixth and seventh decades of life, and two patients and one patient in their eighth and ninth decades respectively (table 1). In one instance (case 19) two biopsy specimens were studied, of which the second specimen was taken three months after the first (or one month after subsidence of the jaundice), while in another (case 25) a biopsy and an autopsy specimen were examined which were obtained 23 days apart. Two biopsy and two autopsy specimens (cases 7, 14, 16, and 21) were from patients treated for jaundice at the Mount Sinai Hospital, New York, whereas most of the other specimens were supplied by other hospitals from all sections of the United States.

The clinical and laboratory data reported were secured by analysis of the entries made in questionnaires submitted by Hoffmann-LaRoche, Inc., to the clinicians who attended the patients included in the study. The findings in the biopsy and autopsy specimens of several patients who had received iproniazid, but did not develop jaundice and did not

---

From the Department of Pathology, the Mount Sinai Hospital.

exhibit symptoms of liver disease, were not included in the study, since these specimens did not show structural abnormalities. Moreover, one patient, who under treatment with iproniazid developed jaundice which subsided and on whom a biopsy was performed several months later, was omitted since hepatitis was not evident in the specimen examined. Hematoxylin-eosin stains and, in addition, where possible, reticulum impregnations and chromotrope/aniline blue stains were used to study the sections.

Results

The cases studied by either biopsy or autopsy can be divided, from the morphologic viewpoint, into several groups.

Biopsy Specimens.—The study of biopsy specimens resulted in a division of the cases into two main groups.

Severe Spotty Necrotic Hepatitis (Cases 9, 11, 12, 16, 17, and 19A): The liver cell plates were interrupted throughout the lobule by necrosis of single cells or small groups of liver cells which were replaced by aggregations of histiocytes and lymphocytes with a varying admixture of segmented leukocytes, some of which were eosinophilic (fig. 1A). The persisting liver cells varied greatly in size and staining qualities. Some were conspicuously enlarged and their cytoplasm was rarefied (ballooned cells); others were smaller and exhibited a dense cytoplasm, while a third type of cell had strongly acidophilic cytoplasm and a pyknotic or broken nucleus. These cells were often expelled from the liver cell plate and were seen as refractile globules in the tissue spaces (acidophilic bodies) (fig. 1*B*).

Other liver cells showed conspicuous evidence of regeneration. The variation in the appearance of the cells in the same area was the outstanding feature of the process. The Kupffer cells were mobilized and contained, as did intralobular macrophages, much brown lipofuscin pigment, apparently derived from liver cell breakdown. The sinusoids were dilated in places but more often they were obstructed by protein debris intermixed with exudate cells. Many bile canaliculi were dilated and contained bile plugs (fig. 1C). Extracellular bile droplets were also seen. The thickened wall of the central vein frequently harbored similar exudate cells. The enlarged and edematous portal tracts

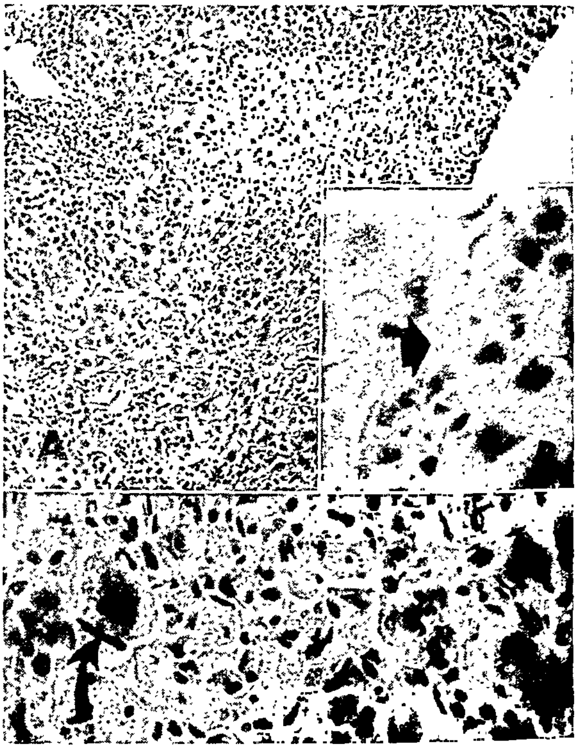

Fig. 1.—Photomicrographs of liver biopsy specimens of patients who developed jaundice after intake of iproniazid (hematoxylin and eosin stain). *A* (case 12), acute spotty necrotic hepatitis with severe interstitial and portal inflammation and regeneration of individual cells (120×). *B*, acidophilic body lying in tissue space containing pyknotic nucleus (*arrow*) (400×). *C*, interstitial accumulation of lymphocytes and macrophages containing lipofuscin around liver cells varying greatly in appearance and bordering on bile plugs in bile capillary (*arrow*) (240×).

exhibited exudate cells—including lipofuscin and bile pigment carrying macrophages. The borders of the portal tracts were obscured by proliferation of ductules, some of which contained bile plugs and exudate cells in their irregularly widened lumens. The duration of jaundice up to the time of biopsy varied in these cases from 5 to 30 days. In one instance a second biopsy after subsidence of jaundice (case 19B) revealed only portal and periportal proliferation of ductules surrounded by fibrosis and exudate cells.

Severe Spotty Necrotic Hepatitis with Extensive Necrosis (cases 7, 20, and 25A): Extensive areas of necrosis were seen in addition to the changes described above. Particularly in the centrolobular zone, liver cells had disappeared from large contiguous areas, and the stroma was collapsed around the persisting mesenchymal elements (fig. 2A). In one patient (case 25A) who subsequently died with subacute hepatitis, the collapse involved whole lobules, the outlines of which were marked by periportal ductular proliferations. The accentuated liver cell breakdown was indicated in all these cases by a very heavy accumulation of lipofuscin both in the Kupffer cells and the macrophages. The jaundice had set in 8 to 30 days before the biopsy was done.

In one instance of mild spotty necrotic hepatitis (case 8), the lesions were similar to those in the first group except that the hepatocellular degeneration, necrosis, and inflammatory reaction were far less severe, although the jaundice was of similar duration. In a subsiding hepatitis (case 5), cellular degeneration and inflammatory lesions in the parenchyma were subdued, while the portal tracts still showed the same pathological picture described above. Lipofuscin pigmentation of the Kupffer cells and regeneratory processes of the liver cells were conspicuous. The total dose of iproniazid administered was the smallest and the duration of therapy the shortest in the entire group. However, this patient had been exposed to cases of jaundice, probably of infectious origin. This raises the question as to whether this patient might not have had infectious hepatitis.

In a case of subacute hepatitis (case 18), the centrolobular zone exhibited severe bile stasis, hepatocellular degeneration, and necrosis (fig. 2B), while in the intermediate zone regeneration with multinucleated giant cells and acidophilic bodies were noted. The portal tracts contained cellular exudate and were fibrotic and connected with each other, producing perilobular fibrosis. The patient had become jaundiced only 24 days before the biopsy was performed.

Autopsy Specimens.—A study of autopsy specimens resulted in a division of the cases into two main groups.

Acute Massive and Submassive Necrotic Hepatitis (cases 1, 3, 6, 10, 13, 24, 26, and 27): In large areas of the liver, all epithelial cells had disappeared in whole lobules or in large parts of them. The framework was either entirely collapsed or was kept still somewhat expanded by erythrocytes which were frequently pooled, or by a mixture of proliferated Kupffer cells with macrophages, both of which contained lipofuscin and occasionally bile pigment. These cells were interspersed to a varying degree with lymphocytes, plasma cells, and neutrophilic and eosinophilic segmented leukocytes (fig. 3A). The reticulum framework itself was intact even where closely approximated. Fragments of the preexisting lobules revealed liver cell plates with dense fat-free cytoplasm. Occasionally, beginning regeneration was indicated by formation of liver cell plates which were several cells thick. On the border of the preserved parts of the parenchyma, the liver cells disintegrated completely, passing through a stage of heavy vacuolization apparently produced by fat deposition; acidophilic bodies were also present. The acuity of the process was indicated by the absence of liver cell breakdown products.

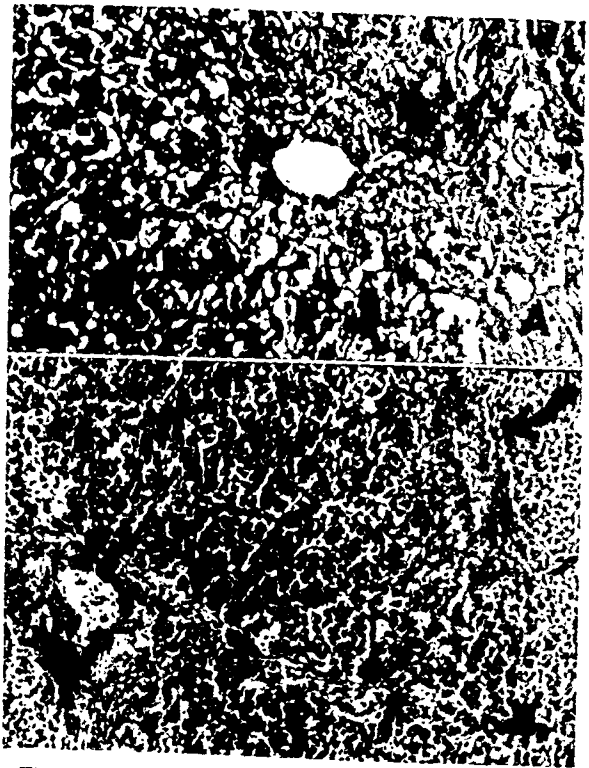

Fig. 2.—Photomicrographs of liver biopsy specimens of patients who developed jaundice after intake of iproniazid (hematoxylin and eosin stain). *A* (case 20), severe spotty necrotic hepatitis with extensive centrolobular necrosis and collapse of framework around central vein (*arrow*) (120×). *B*, (case 18), subacute hepatitis with bile stasis around central vein which exhibits inflammatory infiltration in its wall (*straight arrow*). Perilobular fibrosis (*curved arrow*) connects portal tracts (63×).

Toward the periphery of the lobules many bile ductules, arranged in cords and plates, were lined by irregular epithelial cells which sometimes piled up, formed giant cells, and seemed to be derived from liver cells. The lumens of the ductules contained bile casts and protein-rich exudate intermixed with segmented leukocytes which, with other inflammatory cells, also accumulated around the ductules (fig. 3*B*). These ductular structures indicated the border of the otherwise deepithelialized, collapsed "ghost" lobules. Their center frequently exhibited a thickened hepatic vein branch infiltrated by exudate cells. This apparently fulminant type of hepatic necrosis was observed after 10 to 12 days of jaundice.

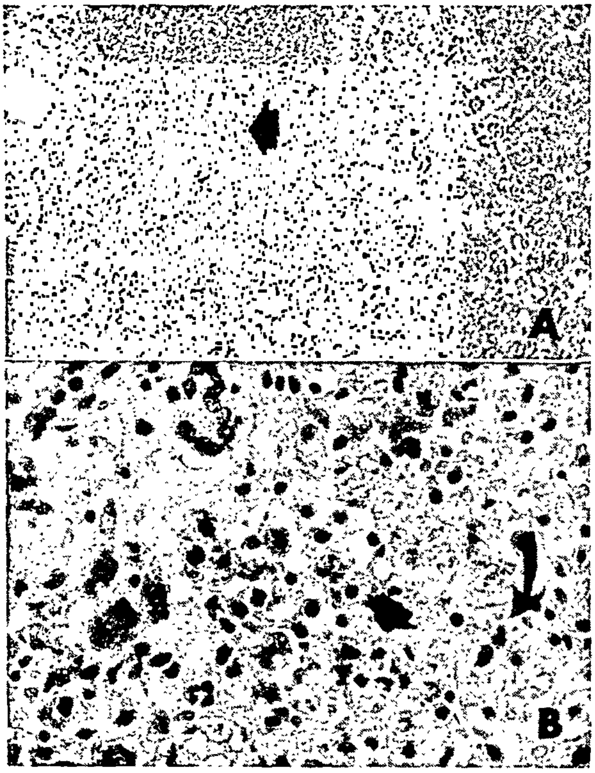

Fig. 3.—Photomicrographs of liver autopsy specimens of patients who developed jaundice after intake of iproniazid. *A* (case 3), fulminant type of massive necrotic hepatitis; collapse and accumulation of red blood cells in central and intermediary zone around hepatic vein branch exhibiting inflammatory infiltration (*arrow*), the periphery of the lobule marked by ductular proliferations (40×). *B*, proliferated ductules and scavenger cells (*straight arrow*) as well as vacuolated degenerating liver cells (*curved arrow*) (240×).

Subacute Hepatitis with Massive and Submassive Collapse (cases 2, 14, 15, 21, 22, and 25B): The lobular architecture, although basically almost always intact, was obscured by degeneration and necrosis, collapse, and regeneration. In the degenerated areas, the cytoplasm of the liver cells was irregular, clumped, bile-pigmented, and vacuolated. Acidophilic bodies were seen in some instances, and the mesenchymal response in three of these cases resembled somewhat that seen around the areas of spotty necrosis in the biopsy material. However, the degree of the inflammatory reaction was remarkably less than in comparable biopsy material. The accumulation of lipofuscin pigment was of equa degree. The collapsed areas usually involved the central zones as well as the immediate periporta area of the parenchyma.

In addition, slits of collapsed parenchyma produced septums linking central zones with each other as well as with portal tracts and dissected portions of the lobules (fig. 4). The collapse appeared recent since the wavy collagenous membranes of the collapsed zones in connective tissue stain were differentiated from the heavy connective tissue bundles of the preformed portal tracts. The isolated portions of the parenchyma exhibited conspicuous regeneration, with giant cells and plates that were two or more cells thick in places where there was still degeneration and necrosis as well as bile stasis. In some of these nodules, the liver cell plates were rearranged concentrically to present the typical regenerative nodules of cirrhosis. Bile ductules often connecting with liver cells were just as

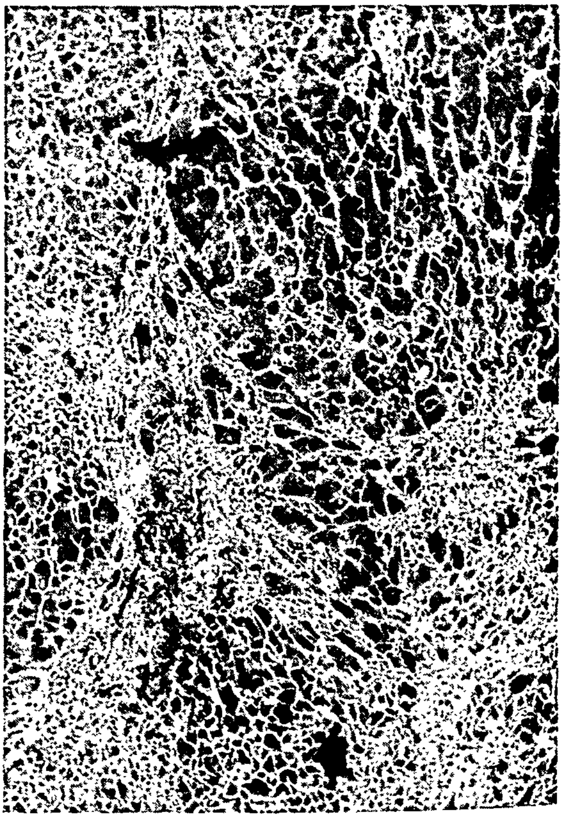

Fig. 4 (case 21).—Photomicrograph of liver autopsy specimen of patient who developed jaundice after intake of iproniazid. Subacute hepatitis existed with submassive collapse, acute degeneration (*straight arrow*), and beginning nodular regeneration and bile stasis (*curved arrow*) (hematoxylin and eosin stain) (63×).

prevalent as in the acute group. Frequently their lumens appeared dilated by large dense microcalculi, and, in two instances, bile infarcts were esent. The nodular transformation of the parenyma represented transition into early postnecrotic rrhosis, but in most instances broad areas of acute assive collapse were still present. Jaundice had en present from 17 to 53 days.

Two cases (cases 4 and 23), which were of shorter duration, presented a transition between both groups. In these specimens necrosis and collapse were observed in the centrolobular and periportal areas, while spotty necrotic changes were seen in the remainder of the parenchyma.

The results of some hepatic tests are available in 25 of the 27 patients (table 2). The total serum bilirubin level was elevated in all patients for whom findings were reported. In 11 of the fatal cases and in 5 of the nonfatal cases, the bilirubin values exceeded 15 mg. per 100 ml. of serum close to the time at which specimens for pathological examination were obtained. In one instance (case 2) the bilirubin value 10 days before death of the patient was almost three times that recorded preterminally. In five other fatal instances (cases 1, 3, 10, 13, and 25), bilirubin levels rose progressively. In five nonfatal cases (5, 7, 12, 16, and 19) records are available of the return of bilirubin levels, as well as of the abnormal findings in other hepatic tests, to normal as these patients recovered, except for prolonged elevation of sulfobromophthalein retention in case 19. At least in one instance (case 11) the bilirubin value remained above 20 mg. per 100 ml. for one month.

§ This patient died subsequently.
‖ Data not available.

Clinical and Laboratory Findings

The clinical manifestations of the four patients observed uniformly in one institution [4f] and of the patients on whom pertinent information was obtained by questionnaires were those of diffuse parenchymal liver disease, mostly without fever. Hepatomegaly was present in a large number of cases. Sometimes the liver was tender and shrank in the preterminal period. To our knowledge, two of the patients studied by biopsy died subsequently (cases 17 and 25A). From the latter patient (case 25B) an autopsy specimen was also obtained. Hepatic coma seemed to have been present in all fatal cases.

Cephalin flocculation was 3+ or 4+ in 12 of 17 patients for whom values were reported. Thymol turbidity, which was above 4 units in 16 of 20 patients, exceeded 15 units in 5 instances. The serum activity of alkaline phosphatase was outside the normal range in 16 of the 20 patients in whom results were available. The values of transaminase which were reported for 15 patients were all elevated with the exception of that in one patient (case 5). However, in one instance, the elevated transaminase value decreased to within normal limits at the time of the second biopsy (case 19B). In three patients (cases 2, 13, and 27) transaminase values dropped precipitously before death. One patient (case 18), with a very high transaminase value, was known to have had jaundice about seven years ago. Significant aberrations of red and white blood cell counts were not reported in any of the cases.

Iproniazid Intake

The total amounts of iproniazid administered to the individual patients ranged from 600 to 19,200 mg. (table 1). In the fatal cases the average total dose, the average duration of medication, and the average daily dose per patient were 5,672 mg., 61.9 days, and 106.7 mg. respectively. In the nonfatal cases the corresponding figures were 3,484 mg., 47.4 days, and 80.5 mg. respectively. The difference in total iproniazid intake between fatal and nonfatal cases is statistically insignificant ($p < 0.3$).

In most instances, iproniazid therapy was discontinued on the onset of jaundice, but in a few patients drug administration was continued for a few days after the icterus had developed. Contrariwise, in one fatal case and in one nonfatal case, therapy was stopped 12 days and 20 days, respectively, prior to the development of jaundice. Moreover, one patient (case 4), who received an average daily dose of 102 mg. for 31 days, died, but another patient (case 8), who was given an average daily dose of 118 mg. for 102 days, survived.

Comment

The presented cases of fatal and nonfatal jaundice occurring after iproniazid therapy raise the following questions: 1. Are the hepatic lesions sufficiently uniform to indicate a single, well-defined disease process? 2. What is the basic pathology? 3. What is the relation between structural alterations of the liver and the clinical manifestations? 4. What is the relation between the iproniazid dose and the severity of the hepatic lesions. 5. What causal relationship between iproniazid administration and these lesions can be assumed?

When jaundice develops after administration of a drug or during the course of a disease, pathological study frequently uncovers a variety of lesions, some of which appear not related to the drug or the disease in question but rather have coincidental causes, e. g., biliary tract disease. In contrast, the cases described here represent a uniform pathological process which varies only in the severity and duration of the lesions. No morphologic evidence of a preexisting liver disease was found. Features predominant in the autopsy specimens were observed in the biopsy specimens and vice versa, suggesting transitional stages between fatal and nonfatal cases. Such stages are usually not as clear in other material of hepatitis.

Basically, the lesion may be described as a diffuse hepatocellular injury with associated inflammatory reaction and bile stasis. The lesion seems to proceed from single cell necrosis to diffuse necrosis with subsequent collapse of whole lobules, particularly in autopsy specimens. A submassive necrosis may leave parts of the parenchyma intact, which may undergo transformation into nodules. Then, features of cirrhosis, such as regenerative nodules and connective tissue septums linking portal tracts and central fields, become apparent, and, in a few cases, the diagnosis of active postnecrotic cirrhosis is justified. Because of the presence of relatively well-preserved parenchyma, it would appear that in these instances the fatal hepatic failure may have been caused by cholestasis reflected in bile infarcts rather than by the loss of liver cells.

The picture of the hepatitis as described above is dissimilar to that usually associated with the exposure to chemicals and which is reproducible in animals.[5] In such lesions, produced, for example, by carbon tetrachloride intoxication, one zone of the liver lobule is characteristically involved, and neighboring liver cells have a similar appearance. Such a picture is to be expected with a poison which has a metabolic effect and is uniformly distributed through the blood stream. Moreover, in toxic hepatitis, fatty metamorphosis is usually prominent, large cell breakdown products are abundant, and the inflammatory response, if present, is subdued and mainly characterized by segmented leukocytes.

In the cases under study, however, the diffuse distribution of the lesion and the conspicuous differences from cell to cell in the spotty necrotic stages would be more in keeping with an infectious process in which the causative agent grows at different rates in various cells. Such changes are typical, for instance, of the usual form of viral hepatitis. While viral hepatitis is not characterized by a single histological finding, a combination of several changes is taken as suggestive evidence for this disease.[6] Confirmation will be available when etiological tests have been developed.

The cases presented reveal all the pathological features of viral hepatitis listed in the classic description of both the nonfatal spotty necrotic form[8] and the fatal, usually massive necrotic form[7] of this disease. In this respect, the following findings in the material presented should be emphasized: the sparsity of breakdown products of hepatic cells in the necrosis; the early tendency of individual liver cells to regenerate; the mononuclear inflammatory reaction with frequent admixture of eosinophils; and the conspicuous ductular proliferation and lipofuscin deposition, as well as the presence of acidophilic bodies in 17 cases and of phlebitis of the hepatic vein branches in 16 instances.

In keeping with these morphologic observations, the clinical picture is also that of a diffuse involvement of the hepatic parenchyma. Various gradations of the process are observed, including fatal hepatic insufficiency characterized by coma. Examples of recovery as well as of chronicity have been substantiated histologically. Viral hepatitis is known to produce a great variety of clinical pictures[8] which makes it difficult to decide on clinical grounds whether viral hepatitis is present in a patient with diffuse hepatic involvement. Several features in this series are not common in the usual type of viral hepatitis. First, fever was frequently absent. Second, jaundice was, on the average, deeper than usually seen. Third, the histological alterations in the biopsy specimens of the patients with jaundice after iproniazid administration were far more severe than in a random material of viral hepatitis, but this may be an incidental result of sampling. However, the histological alterations are also more severe than would be expected from the clinical manifestations. Particularly, the collapse of contiguous parts of the parenchyma is not often observed in biopsy specimens from patients with viral hepatitis. Many clinicians are hesitant to perform liver biopsy in the presence of such changes. Finally, the high incidence of fatality, which often occurs with a fulminant course, indicates a much higher mortality than in the usual type of viral hepatitis, particularly in younger age groups. The numerical relation of autopsy to biopsy specimens in this material does not reflect the actual mortality, because autopsy specimens are more readily available than biopsy specimens. However, it is a safe assumption that the mortality is many times higher than that in viral hepatitis which, in the United States, is between 0.5 to 1%.[9]

The laboratory findings also support the concept of a diffuse disorder of the hepatic parenchyma in contrast to the hepatitis of the cholestatic type, such as may follow the administration of chlorpromazine.[1] However, in contrast to the situation in usual cases of viral hepatitis, cephalin flocculation is not quite as often abnormal and the thymol turbidity is less frequently very high. This has been considered characteristic of the serum type of hepatitis.[8] The frequent absence of febrile manifestations as well as the greater severity of the disease process, including a higher mortality and a more rapid course, have been observed[10] in some types of serum hepatitis, particularly when it occurs in elderly women.

The information on the dosage of iproniazid used in the cases presented was obtained mainly by means of a questionnaire. Taking these data at their face value, it is evident that the average total drug intake and the average daily dose were greater and that the average duration of drug therapy was longer in the fatal than in the nonfatal cases. However, the lack of statistical significance of these differences speaks against a definite relationship between the size of the daily dose and the duration of treatment with iproniazid on the one hand and the severity and outcome of the hepatitis on the other. A similar situation seems to exist with cinchophen, the administration of which is also associated with a very low incidence of hepatic necrosis of high mortality, without evidence of a relationship between dose and extent of lesion.[11]

In an attempt to clarify the possible etiological relation between iproniazid administration and the hepatic lesions observed, several possibilities must be considered. First, the hepatic disease may be not caused by iproniazid but is rather coincidental and may, for instance, be a viral infection transmitted by a poorly sterilized needle used in the course of other therapeutic procedures. This has been thought to be a possibility in the jaundice that occurs after administration of cinchophen.[11] However, it seems that the incidence of liver damage is much higher in these patients than in patients who were treated with other drugs and may have received parenteral therapy.

A second possibility is that iproniazid may produce a toxic effect which is indistinguishable from viral hepatitis. Acute yellow atrophy, resembling viral hepatitis, has been reported in a very low incidence after the administration of other drugs, e. g., sulfonamides[12] or zoxazolamine.[13] Thus, some drugs may produce occasionally the same metabolic changes as a virus, or both might elicit the same hyperergic reaction.

Before the inability to differentiate pathologically viral and toxic hepatitis is conceded, a third possibility should at least be considered, namely, that iproniazid activates subclinical viral hepatitis, particularly of the serum type (type SH or B). It is conceivable that this drug would produce an active disease process in a carrier. In view of the relatively low incidence of hepatitis in patients treated with iproniazid, it is apparent that not every carrier would develop jaundice if exposed to iproniazid. Further studies on the hepatitis associated with iproniazid therapy may throw new light on the mechanism of infection in viral hepatitis.

Because of the clinical and pathological similarity between the jaundice that occurs after administration of iproniazid and that which results from viral

doctors try to limit themselves to those surgical procedures that are more consistent with their training and experience.

The following suggestions brought out by the tissue committee have been adopted by our hospitals: (1) a uniform code for the sterilization of patients in one of our hospitals, (2) the routine performance of proctoscopic or sigmoidoscopic examination prior to hemorrhoid operations, (3) the routine pathological examination of all tissues removed at operation except tonsils, and (4) the routine performance of total hysterectomy rather than subtotal hysterectomy except in rare instances. The improvements brought out by the activity of the tissue committee have stimulated the staff at one hospital to appoint a medical audit committee and to hold a monthly death conference.

Defects of Committee

On the other hand, it is recognized that abuses can occur in the functioning of a tissue committee. Medicolegal hazards may possibly develop, and malpractice suits could be generated by the actions of the committee. It is our feeling that the record of its activities should not be preserved except in tabular form, thereby preventing the identification of the action of the tissue committee in any given case, and that use of specific names of staff members be avoided. This practice of not keeping identifiable records may not fully meet the requirements of the Joint Commission, but we hope they will recognize this legal implication and act accordingly. Physicians should be advised to be discreet and not to discuss the specific activities of the tissue committee among themselves in the presence of curious hospital personnel, since this might lead to misunderstanding and malicious gossip. close to each other and do not like to criticize the work of others. In such instances, it is suggested that doctors from other hospitals be asked to serve on the tissue committee.

Some small hospitals do not have pathologists on their staffs. A pathologist is not indispensable, although his findings usually are a definite aid. Most physicians accept the findings of the tissue committee with dignity. Many have been heard to say that they learn more from these reports and discussions than from any other one meeting that they attend.

Statistical Data

The following statistical data demonstrate some of the problems and results encountered in our program. From 1953 to 1957, a total of 219 gallbladders were removed in one of our hospitals. Of these, 185 (85%) were pathological. Improvement is needed here, but without the work of the tissue committee we would not have known it. In another hospital 95 gallbladders were removed in the same period. Of these, 92% were found to be pathological.

The appendectomies done in a hospital always seem to reflect in some manner the surgery being done. In 1956 in one hospital 107 appendectomies were performed; 70 (66%) were pathological. In another hospital 111 appendectomies were done; 72 (65%) were pathological. In a third hospital 153 appendectomies were performed; 126 (82%) were pathological. Table 1 gives records kept in one hospital for physicians who did five or more appendectomies from 1954 to 1957. The appendix was judged pathological if any type disease was found by the pathologist.

In the field of pelvic surgery, in one hospital 41 suspensions were performed in 1951, 25 in 1952, 30 in 1953, 14 in 1954, and 10 in 1955. At another hospital 36 suspensions were performed in 1950 and only 4 in 1956. The following table shows the decline in subtotal hysterectomies performed.

Since the records in our hospitals prior to the formation of the tissue committees are not adequate, many true relationships cannot be shown.

Give the tissue committee executive power. 2. The tissue committee should be composed of doctors who have proper training and/or experience, and who are willing to actively work on the committee in an absolutely unbiased manner. 3. Full surgical privileges should not be granted to inadequately trained and inadequately experienced physicians; every staff member should be granted privileges according to his demonstrated competence regardless of the certificates he may hold. 4. Similar committees should be formed in other departments, such as medicine and obstetrics. 5. Local control of the practice of medicine and surgery is far better than control from Washington, Chicago, or elsewhere. 6. If no pathologist is available, the tissue committee should function just as effectively. 7. If the staff is too small to have an effective committee, neighboring doctors should be asked to serve on such a committee. It is obvious that the work of the tissue committee in hospitals has improved the quality of patient care.

EFFECT OF AIR FLOW RESISTANCE ON VENTILATION AND RESPIRATORY MUSCLE ACTIVITY

B. Raymond Fink, M.D., Shih-Hsun Ngai, M.D.
and
Duncan A. Holaday, M.D., New York

As measured in decerebrate cats, inspiratory air flow resistance initially reduces the tidal volume and frequency of respiration. The reduction in tidal volume is aggravated by pentobarbital, nitrous oxide, or ether. If the flow resistance persists, there is a gradual recovery in the volume of ventilation, but even in the unanesthetized state this is not complete at the end of five minutes. Ventilation is reduced with increased airway resistance in spite of augmented muscular activity. The reduction of ventilation is proportional to the magnitude of the resistance.

Although there is general agreement that increased resistance to air flow has an adverse effect on ventilation, there have been very few quantitative studies of this subject. Recently it was reported[1] that in man an added airway resistance maintained for five minutes caused a reduction in pulmonary ventilation and a rise in alveolar carbon dioxide tension. The object of the present study was to measure the effect of air flow resistance on ventilation and diaphragmatic muscular activity. The influence of anesthetic agents on the response to increased airway resistance was also investigated.

Method

Studies were made on decerebrate cats in order to obtain continuous observation of the unanesthetized and anesthetized states. Decerebration was performed at midcollicular level during diethyl ether anesthesia. Measurements were made one hour or more after the completion of decerebration, at which time the preparation was stable and most of the ether eliminated. Control observations were made while the animals breathed room air. Nitrous oxide–oxygen or diethyl ether oxygen mixture was introduced through a non-rebreathing valve. Pentobarbital sodium in divided doses was administered intravenously.

Recordings were made with the use of five channels of an eight-channel cathode-ray oscillograph. The tidal volume was measured with a small animal pneumotachograph and displayed on one channel of the recorder, the output of which was integrated electronically, with use of a second channel. The airway pressure was obtained with a strain-gauge transducer. The action potentials of the diaphragm from two monopolar electrodes inserted through the ninth intercostal space were amplified and recorded on the fourth channel. In addition, the electromyogram was integrated on the fifth channel, thus providing an estimate of total electrical activity as well as the frequency of dis-

Read before the Section on Anesthesiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

doctors try to limit themselves to those surgical procedures that are more consistent with their training and experience.

The following suggestions brought out by the tissue committee have been adopted by our hospitals: (1) a uniform code for the sterilization of patients in one of our hospitals, (2) the routine performance of proctoscopic or sigmoidoscopic examination prior to hemorrhoid operations, (3) the routine pathological examination of all tissues removed at operation except tonsils, and (4) the routine performance of total hysterectomy rather than subtotal hysterectomy except in rare instances. The improvements brought out by the activity of the tissue committee have stimulated the staff at one hospital to appoint a medical audit committee and to hold a monthly death conference.

Defects of Committee

On the other hand, it is recognized that abuses can occur in the functioning of a tissue committee. Medicolegal hazards may possibly develop, and malpractice suits could be generated by the actions of the committee. It is our feeling that the record of its activities should not be preserved except in tabular form, thereby preventing the identification of the action of the tissue committee in any given case, and that use of specific names of staff members be avoided. This practice of not keeping identifiable records may not fully meet the requirements of the Joint Commission, but we hope they will recognize this legal implication and act accordingly. Physicians should be advised to be discreet and not to discuss the specific activities of the tissue committee among themselves in the presence of curious hospital personnel, since this might lead to misunderstanding and malicious gossip.

close to each other and do not like to criticize the work of others. In such instances, it is suggested that doctors from other hospitals be asked to serve on the tissue committee.

Some small hospitals do not have pathologists on their staffs. A pathologist is not indispensable, although his findings usually are a definite aid. Most physicians accept the findings of the tissue committee with dignity. Many have been heard to say that they learn more from these reports and discussions than from any other one meeting that they attend.

Statistical Data

The following statistical data demonstrate some of the problems and results encountered in our program. From 1953 to 1957, a total of 219 gallbladders were removed in one of our hospitals. Of these, 185 (85%) were pathological. Improvement is needed here, but without the work of the tissue committee we would not have known it. In another hospital 95 gallbladders were removed in the same period. Of these, 92% were found to be pathological.

The appendectomies done in a hospital always seem to reflect in some manner the surgery being done. In 1956 in one hospital 107 appendectomies were performed; 70 (66%) were pathological. In another hospital 111 appendectomies were done; 72 (65%) were pathological. In a third hospital 153 appendectomies were performed; 126 (82%) were pathological. Table 1 gives records kept in one hospital for physicians who did five or more appendectomies from 1954 to 1957. The appendix was judged pathological if any type disease was found by the pathologist.

In the field of pelvic surgery, in one hospital 41 suspensions were performed in 1951, 25 in 1952, 30 in 1953, 14 in 1954, and 10 in 1955. At another hospital 36 suspensions were performed in 1950 and only 4 in 1956. The following table shows the decline in subtotal hysterectomies performed.

Since the records in our hospitals prior to the formation of the tissue committees are not adequate, many true relationships cannot be shown. Also, one of the hospitals is new and no prior records are available. Even so, improvement from a surgical standpoint can be seen.

USES AND ABUSES OF THE TISSUE COMMITTEE

Paul G. Henley, M.D., Kenneth R. Duzan, M.D., El Dorado, Ark.
and
Rufus B. Robins, M.D., Camden, Ark.

A tissue committee is a group of physicians chosen within a hospital to review the histories of patients from whom tissues have been removed surgically; its purpose is to give an opinion on the correctness of the diagnosis and treatment. Data show that in the past there has been a marked diversity of practice among surgeons, with a lack of demonstrable abnormality in more than half of the appendixes removed by some surgeons. Since the formation of tissue committees, many improvements have been noted in the thoroughness of physical examinations, frequency of consultation, quality of operation, and preoperative and postoperative care. There has been a decrease in the frequency of subtotal hysterectomies, suspensoons of the uterus, ill-advised appendectomies, and other dubious, needless, or exploratory operations. The tissue committee is a device that has defects and dangers; but when made up of qualified, conscientious, and tactful physicians and properly organized with respect to the hospital, it has contributed greatly to the improvement of patient care.

Today most of the hospitals of the United States have some type of a committee, generally known as the tissue committee, set up for the control and evaluation of the surgery being done in a hospital. It is a requirement of the Joint Commission on the Accreditation of Hospitals. The problems in large teaching hospitals and in the smaller open staff hospitals are somewhat different. In this discussion we are referring mainly to the latter. We are working in two hospitals of this type: one has 150 beds and the other 125 beds. It is our purpose to try to point out some of the problems that confront such a committee in these hospitals because the committees are new and because they can do pioneer work if certain limitations are noted.

In the history of medicine, the control of itself for the benefit of others—the public—has always been paramount. In American medicine, the American Medical Association, the Association of Medical Colleges, and the American College of Surgeons, as well as other bodies, have been the forces behind our self-control programs. Today two other organizations, the Joint Commission on the Accreditation of Hospitals and the American Academy of General Practice have joined in this endeavor, not only in surgery but in all aspects of the practice of medicine. It is to be noted also that all of this work, all of this effort, has been exerted in order to control a small minority of doctors. A few individuals although properly trained and experienced are inclined to be unscrupulous. They require supervision and control on the part of conscientious colleagues.

In our particular hospitals the tissue committee is composed of the pathologist, the only continuing member, and three other members of the staff, who serve for a period of one year and are appointed by the chief of staff. Our open staff hospitals admit members of the county medical society to practice in the hospitals and therefore we have all types of physicians with all types of training and experience.

Our tissue committee functions in an advisory capacity only and has no executive powers. Decisions are based on the facts presented by the entire case in question. Neither a pathological ratio nor a strict auditing method is used as the sole criterion for decisions. It does not investigate all cases; for example, the orthopedic cases have not been investigated. It checks the cases where tissue has been submitted for examination. The research may show that, in the opinion of the tissue committee, certain diagnoses are not justified and why. It also brings up cases for open discussion at an executive meeting of the staff. Its findings are kept confidential, in that only members of the committee and the staff members are present at the discussions. Any doctor who has a case up for discussion is notified 24 hours in advance. The committee reports once a month to the staff meeting.

Since the formation of the tissue committees in our hospitals there have been many improvements noted in surgery, such as better records, better preoperative and postoperative care, more consultations, less doubtful and needless surgery, better examination of patients, and a fewer number of so-called exploratory operations. It is difficult for any doctor to exploit, during surgical exploration, the female pelvis, the gall-bladder, or the appendix or to do any questionable surgery without its being known by the tissue committee, who would call his attention to it. It is also noted that most of the

Read before the Section on General Practice at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

hepatitis, it is readily understood why a causal relation between drug therapy and hepatic injury was not suspected until a considerable number of cases had occurred.

Whatever the mechanism, the fact that jaundice and diffuse hepatic injury, usually of great severity, occur in a small number of patients treated with iproniazid must be taken into account when prescribing this drug and invites, just as with other potent drugs, careful evaluation of the limitations, indications, and contraindications of iproniazid. Periodic checking by sensitive hepatic tests might reduce the risk.

Summary

A histological study was made of 13 biopsy specimens and 16 autopsy specimens of livers which were obtained in a nationwide collection from 27 patients who had developed jaundice after the administration of iproniazid (Marsilid) phosphate. The findings were correlated with the clinical manifestations of the hepatic disease and the dose of drug administered. The pathological picture was that of a diffuse hepatic parenchymal disease which ranged from a spotty necrosis of single cells to a diffuse massive necrosis and collapse, both associated with inflammatory infiltration. Tendency to transition into postnecrotic cirrhosis was apparent. The morphologic alterations were those considered characteristic of viral hepatitis. Histological evidence of preexisting liver disease was absent. Also, the clinical manifestations were those of a diffuse parenchymal involvement of the liver, but, in contrast to the usual cases of viral hepatitis, fever was frequently absent, the anatomic lesions were more severe than would be expected from the clinical picture, the jaundice was deeper, the process as a whole was more virulent, the mortality was higher, and the serum protein reactions were not as often altered.

A relationship between the dosage of iproniazid and the extent of the lesion was not evident, and jaundice appeared as late as 20 days after the cessation of therapy. The role which iproniazid may play in producing hepatic lesions is not clear; this is also true of other drugs such as cinchophen. The possibilities have to be considered that drugs such as iproniazid and others may produce morphologic changes previously considered characteristic of viral hepatitis in a low incidence or that these drugs may activate an existing subclinical vital hepatitis, e. g., in a carrier of serum hepatitis. Whatever the causal relation, the possible occurrence of severe hepatic damage with a deceptively less severe clinical picture but with a high mortality should be kept in mind when iproniazid is administered and should be weighed against its definite usefulness in patients with disabling depressions.

Mt. Sinai Hospital, Fifth Avenue and 100th Street (29).

This study was supported by the Jacqueline Armour Memorial Fund for the Study of Hepatic Disease, the Mount Sinai Hospital, New York.

Drs. Leo A. Pirk and Robert Dixon of the department of clinical investigation of Hoffmann-LaRoche, Inc., Nutley, N. J., made available for this study all pathological material collected by them as well as the pertinent information at their disposal. Clinicians and pathologists from many parts of the United States contributed findings and specimens.

USES AND ABUSES OF THE TISSUE COMMITTEE

Paul G. Henley, M.D., Kenneth R. Duzan, M.D., El Dorado, Ark.
and
Rufus B. Robins, M.D., Camden, Ark.

A tissue committee is a group of physicians chosen within a hospital to review the histories of patients from whom tissues have been removed surgically; its purpose is to give an opinion on the correctness of the diagnosis and treatment. Data show that in the past there has been a marked diversity of practice among surgeons, with a lack of demonstrable abnormality in more than half of the appendixes removed by some surgeons. Since the formation of tissue committees, many improvements have been noted in the thoroughness of physical examinations, frequency of consultation, quality of operation, and preoperative and postoperative care. There has been a decrease in the frequency of subtotal hysterectomies, suspensoons of the uterus, ill-advised appendectomies, and other dubious, needless, or exploratory operations. The tissue committee is a device that has defects and dangers; but when made up of qualified, conscientious, and tactful physicians and properly organized with respect to the hospital, it has contributed greatly to the improvement of patient care.

Today most of the hospitals of the United States have some type of a committee, generally known as the tissue committee, set up for the control and evaluation of the surgery being done in a hospital. It is a requirement of the Joint Commission on the Accreditation of Hospitals. The problems in large teaching hospitals and in the smaller open staff hospitals are somewhat different. In this discussion we are referring mainly to the latter. We are working in two hospitals of this type: one has 150 beds and the other 125 beds. It is our purpose to try to point out some of the problems that confront such a committee in these hospitals because the committees are new and because they can do pioneer work if certain limitations are noted.

In the history of medicine, the control of itself for the benefit of others—the public—has always been paramount. In American medicine, the American Medical Association, the Association of Medical Colleges, and the American College of Surgeons, as well as other bodies, have been the forces behind our self-control programs. Today two other organizations, the Joint Commission on the Accreditation of Hospitals and the American Academy of General Practice have joined in this endeavor, not only in surgery but in all aspects of the practice of medicine. It is to be noted also that all of this work, all of this effort, has been exerted in order to control a small minority of doctors. A few individuals although properly trained and experienced are inclined to be unscrupulous. They require supervision and control on the part of conscientious colleagues.

In our particular hospitals the tissue committee is composed of the pathologist, the only continuing member, and three other members of the staff, who serve for a period of one year and are appointed by the chief of staff. Our open staff hospitals admit members of the county medical society to practice in the hospitals and therefore we have all types of physicians with all types of training and experience.

Our tissue committee functions in an advisory capacity only and has no executive powers. Decisions are based on the facts presented by the entire case in question. Neither a pathological ratio nor a strict auditing method is used as the sole criterion for decisions. It does not investigate all cases; for example, the orthopedic cases have not been investigated. It checks the cases where tissue has been submitted for examination. The research may show that, in the opinion of the tissue committee, certain diagnoses are not justified and why. It also brings up cases for open discussion at an executive meeting of the staff. Its findings are kept confidential, in that only members of the committee and the staff members are present at the discussions. Any doctor who has a case up for discussion is notified 24 hours in advance. The committee reports once a month to the staff meeting.

Since the formation of the tissue committees in our hospitals there have been many improvements noted in surgery, such as better records, better preoperative and postoperative care, more consultations, less doubtful and needless surgery, better examination of patients, and a fewer number of so-called exploratory operations. It is difficult for any doctor to exploit, during surgical exploration, the female pelvis, the gall-bladder, or the appendix or to do any questionable surgery without its being known by the tissue committee, who would call his attention to it. It is also noted that most of the

22	86	5	20
20	85		

Defects of Committee

On the other hand, it is recognized that abuses can occur in the functioning of a tissue committee. Medicolegal hazards may possibly develop, and malpractice suits could be generated by the actions of the committee. It is our feeling that the record of its activities should not be preserved except in tabular form, thereby preventing the identification of the action of the tissue committee in any given case, and that use of specific names of staff members be avoided. This practice of not keeping identifiable records may not fully meet the requirements of the Joint Commission, but we hope they will recognize this legal implication and act accordingly. Physicians should be advised to be discreet and not to discuss the specific activities of the tissue committee among themselves in the presence of curious hospital personnel, since this might lead to misunderstanding and malicious gossip.

Another point to recognize is that the activities of the tissue committee may make a too conscientious doctor fail to use his better judgment at times. It may lead to undue procrastination, as in cases of surgical abdomens. Some doctors will not accept criticism and insist on their individual rights to practice medicine as they see fit. Some defy the tissue committee and others try too hard to please. Some abuse it by defending other doctors when they definitely need criticism. In small hospitals with few doctors on the staff, the doctors are very close to each other and do not like to criticize the work of others. In such instances, it is suggested that doctors from other hospitals be asked to serve on the tissue committee.

Some small hospitals do not have pathologists on their staffs. A pathologist is not indispensable, although his findings usually are a definite aid. Most physicians accept the findings of the tissue committee with dignity. Many have been heard to say that they learn more from these reports and discussions than from any other one meeting that they attend.

Statistical Data

The following statistical data demonstrate some of the problems and results encountered in our program. From 1953 to 1957, a total of 219 gallbladders were removed in one of our hospitals. Of these, 185 (85%) were pathological. Improvement is needed here, but without the work of the tissue committee we would not have known it. In another hospital 95 gallbladders were removed in the same period. Of these, 92% were found to be pathological.

The appendectomies done in a hospital always seem to reflect in some manner the surgery being done. In 1956 in one hospital 107 appendectomies were performed; 70 (66%) were pathological. In another hospital 111 appendectomies were done; 72 (65%) were pathological. In a third hospital 153 appendectomies were performed; 126 (82%) were pathological. Table 1 gives records kept in one hospital for physicians who did five or more appendectomies from 1954 to 1957. The appendix was judged pathological if any type disease was found by the pathologist.

In the field of pelvic surgery, in one hospital 41 suspensions were performed in 1951, 25 in 1952, 30 in 1953, 14 in 1954, and 10 in 1955. At another hospital 36 suspensions were performed in 1950 and only 4 in 1956. The following table shows the decline in subtotal hysterectomies performed.

Since the records in our hospitals prior to the formation of the tissue committees are not adequate, many true relationships cannot be shown. Also, one of the hospitals is new and no prior records are available. Even so, improvement from a surgical standpoint can be seen.

TABLE 2.—*Hysterectomies Performed in Three Hospitals*

Comment

It is our firm belief that the following recommendations, if adopted, would further aid in developing and maintaining high standards of surgery being done in our smaller open staff hospitals: 1.

Give the tissue committee executive power. 2. The tissue committee should be composed of doctors who have proper training and/or experience, and who are willing to actively work on the committee in an absolutely unbiased manner. 3. Full surgical privileges should not be granted to inadequately trained and inadequately experienced physicians; every staff member should be granted privileges according to his demonstrated competence regardless of the certificates he may hold. 4. Similar committees should be formed in other departments, such as medicine and obstetrics. 5. Local control of the practice of medicine and surgery is far better than control from Washington, Chicago, or elsewhere. 6. If no pathologist is available, the tissue committee should function just as effectively. 7. If the staff is too small to have an effective committee, neighboring doctors should be asked to serve on such a committee. It is obvious that the work of the tissue committee in hospitals has improved the quality of patient care.

EFFECT OF AIR FLOW RESISTANCE ON VENTILATION AND RESPIRATORY MUSCLE ACTIVITY

B. Raymond Fink, M.D., Shih-Hsun Ngai, M.D.
and
Duncan A. Holaday, M.D., New York

As measured in decerebrate cats, inspiratory air flow resistance initially reduces the tidal volume and frequency of respiration. The reduction in tidal volume is aggravated by pentobarbital, nitrous oxide, or ether. If the flow resistance persists, there is a gradual recovery in the volume of ventilation, but even in the unanesthetized state this is not complete at the end of five minutes. Ventilation is reduced with increased airway resistance in spite of augmented muscular activity. The reduction of ventilation is proportional to the magnitude of the resistance.

Although there is general agreement that increased resistance to air flow has an adverse effect on ventilation, there have been very few quantitative studies of this subject. Recently it was reported[1] that in man an added airway resistance maintained for five minutes caused a reduction in pulmonary ventilation and a rise in alveolar carbon dioxide tension. The object of the present study was to measure the effect of air flow resistance on ventilation and diaphragmatic muscular activity. The influence of anesthetic agents on the response to increased airway resistance was also investigated.

Method

Studies were made on decerebrate cats in order to obtain continuous observation of the unanesthetized and anesthetized states. Decerebration was performed at midcollicular level during diethyl ether anesthesia. Measurements were made one hour or more after the completion of decerebration, at which time the preparation was stable and most of the ether eliminated. Control observations were made while the animals breathed room air. Nitrous oxide–oxygen or diethyl ether oxygen mixture was introduced through a non-rebreathing valve. Pentobarbital sodium in divided doses was administered intravenously.

Recordings were made with the use of five channels of an eight-channel cathode-ray oscillograph. The tidal volume was measured with a small animal pneumotachograph and displayed on one channel of the recorder, the output of which was integrated electronically, with use of a second channel. The airway pressure was obtained with a strain-gauge transducer. The action potentials of the diaphragm from two monopolar electrodes inserted through the ninth intercostal space were amplified and recorded on the fourth channel. In addition, the electromyogram was integrated on the fifth channel, thus providing an estimate of total electrical activity as well as the frequency of dis-

---

charge. It is known that under specific conditions the integral of the electromyogram is proportional to the tension developed by the muscle.[2] In the case of the diaphragm the present study suggests that the slope of the integral during inspiration indicates the intensity of the muscular activity required for the observed flow of air.

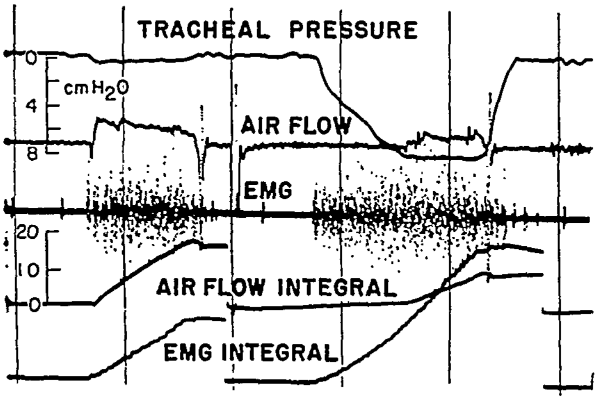

Fig. 1 (cat 27).—Actual record of normal respiration followed by one inspiration against added load of —8 cm. H_2O in unanesthetized cat. Tidal volume is measured by vertical displacement of air flow integral. Electromyogram *(EMG)* shows prolongation of diaphragmatic contraction with application of resistance, and intensity, shown by slope of electromyogram integral, increases until air flow begins, thereafter remaining steady (time lines=one second).

Inspiratory resistance to air flow was introduced by means of a vacuum-cleaner fan connected to the non-rebreathing valve through a three-way tap. The third limb of the tap led to room air or to the anesthetic reservoir. The speed of the fan was regulated by a variable transformer; the magnitude of the negative pressure generated was monitored with a water manometer. The negative pressure, when applied for single breaths by turning the three-way tap, constituted an accurately controlled inspiratory resistance. For the study of continuous inspiratory resistance during inhalation anesthesia, the resistance consisted of an appropriately weighted inspiratory valve. This allowed continued inhalation of the anesthetic mixture so that the depth of anesthesia would not be changed appreciably during the test period.

Eighteen animals were studied and were divided into four groups. In groups 1, 2, and 3, graduated resistances in steps of 2 cm. H_2O were applied for single breaths at one-minute intervals, before and after administration of anesthetics, as follows: group 1 (five cats), pentobarbital sodium given intravenously in successive doses of 6 mg. per kilogram of body weight; group 2 (four cats), 80% concentration of nitrous oxide and 20% concentration of oxygen; and group 3 (four cats), three increasing concentrations of diethyl ether vapor in oxygen. Inhalation of these anesthetic mixtures was maintained for 30 minutes before any measurement was taken so that a relatively steady state was obtained. The ether mixtures were obtained by appropriate dilution of the outflow from a "copper kettle" at the observed temperature. The ether concentration was estimated indirectly with a Pauling oxygen analyzer. In group 4 (five cats), continuous resistance to inspiration was applied for five minutes before and during anesthesia with pentobarbital or ether. Respiratory frequency, tidal volume, and diaphragmatic muscular activity were measured continuously.

Results

Unanesthetized State.—A typical example of the immediate response to increased inspiratory resistance is reproduced in figure 1. This is a record of two successive respirations: first, the control and, second, inspiration against an added resistance of −8 cm. H_2O. In the control breath, the duration of air flow corresponded almost exactly with the period of electrical discharge of the diaphragm and both integrals rose at a steady rate, indicating that the rate of air flow and the intensity of diaphragmatic contraction remained constant throughout most of the inspiratory phase. In the second breath, the air flow volume was diminished and the air flow rate was reduced, as indicated by the height and slope of the integral. The onset of inspiratory air flow was much delayed in respect to the muscular activity. The diaphragmatic contraction was prolonged and increased in intensity, as evidenced by the steeper slope of the electromyographic integral. When the response to a series of increasing air flow resistances was examined, the reduction in tidal volume was proportional to the added resistance, notwithstanding a concomitant proportionate increase in diaphragmatic activity (fig. 2). The fact that the increased diaphragmatic activity occurred immediately on application of the resist-

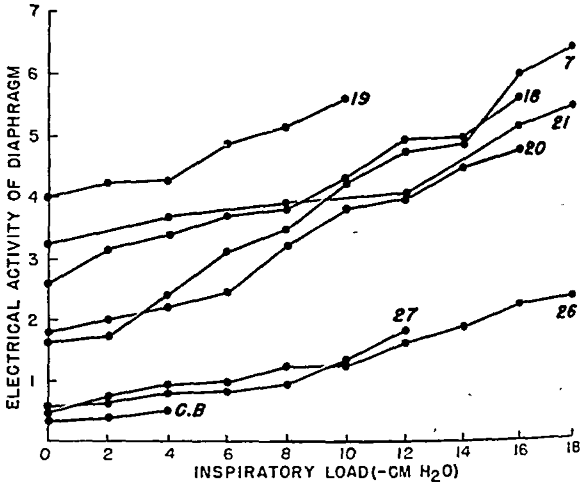

Fig. 2.—Effect of inspiratory resistance on diaphragmatic activity. Voltage output of muscle increases approximately linearly with load; increased activity was not sufficient to maintain normal tidal volume.

ance suggests that this is a reflex phenomenon, probably through the Hering-Breuer stretch reflex, since it was abolished by bilateral vagotomy.

When the resistance was maintained continuously for five minutes, the diaphragmatic activity increased in successive breaths over the first half-minute. The tidal volume decreased initially on application of resistance and recovered gradually during the five-minute period but never to the original level.

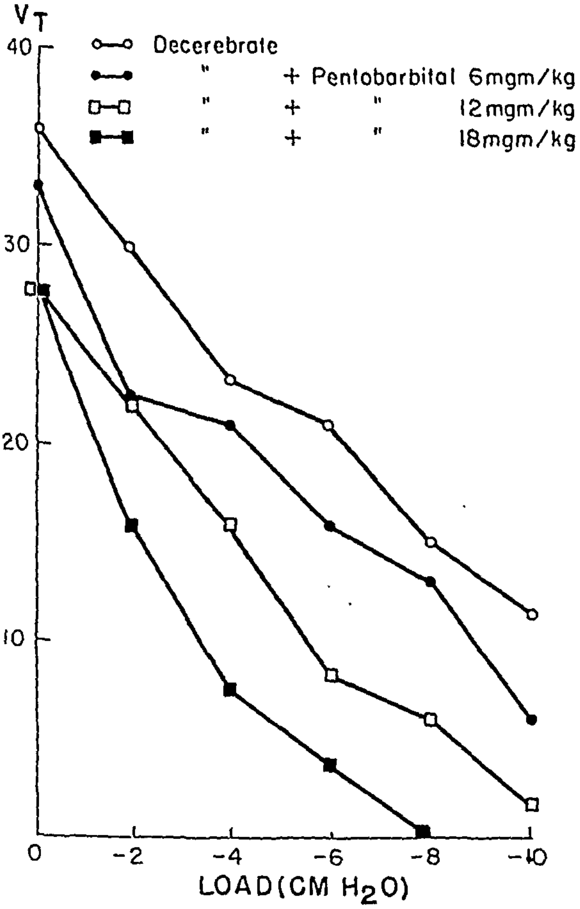

Fig. 3.—Effect of pentobarbital sodium on ventilation during inspiratory flow resistance. Ability to overcome flow resistance decreased as more drug was administered.

Anesthetized State.—The effect of pentobarbital sodium on the immediate response to inspiratory resistance was as follows: The volume and rate of air flow against the added resistance were reduced to a greater extent as compared with those in the unanesthetized animal. The diaphragmatic contraction was prolonged but showed little increase in intensity.

Application of a series of increasing inspiratory resistances caused a reduction in tidal volume proportional to the magnitude of the resistance (fig. 3), the decline occurring more rapidly with each additional dose of pentobarbital. Thus, the fractional decrease in tidal volume produced by a given resistance was relatively greater as the anesthesia was deeper. In this respect, the effects of nitrous oxide and diethyl ether were without exception similar to those of pentobarbital, as shown in figure 4. Evidently, general anesthesia exaggerates the impairment of ventilation caused by inspiratory air flow resistance, and this impairment becomes progressively more pronounced as anesthesia deepens.

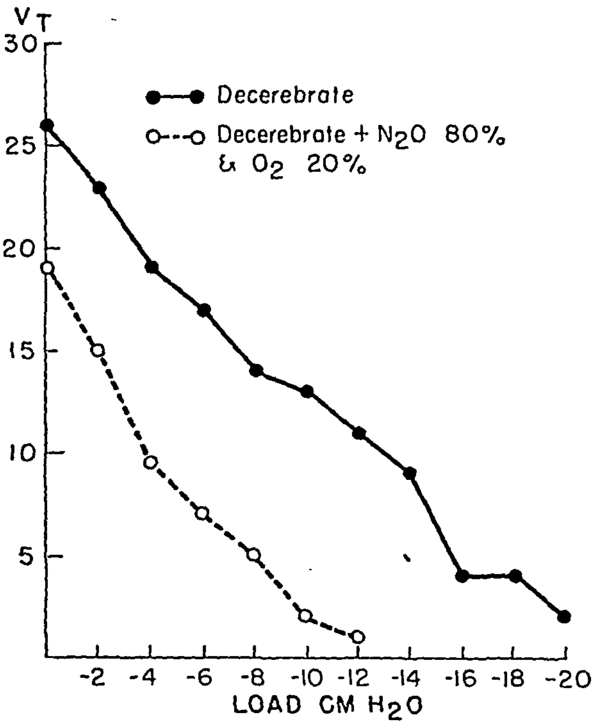

Fig. 4.—Effect of nitrous oxide on ventilation during inspiratory flow resistance, showing depression of tidal volume by anesthesia.

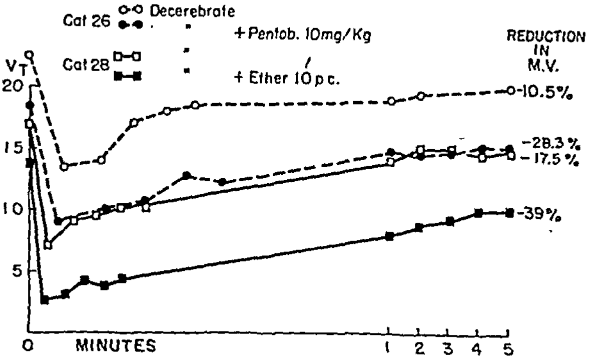

Fig. 5.—Inspiratory resistance of −12 cm. H_2O sustained for five minutes. During pentobarbital and diethyl ether anesthesia, depression of tidal volume by resistance was increased and recovery of minute volume delayed.

The effect of pentobarbital and diethyl ether anesthesia on the adjustment to sustained inspiratory resistance is shown in figure 5. The reduction in minute volume was much greater after the animals were anesthetized (see table). The higher respiratory rate with ether anesthesia apparently did not compensate for decreased tidal volume.

Comment

Relatively high resistances (6-15 cm. H_2O) were used in the sustained resistance experiments in order to produce significant disturbances in a short period of time. Similar but less marked responses were produced with lower resistances, even with the low resistances of clinical anesthesia apparatus. Figure 6 shows the effect on respiratory muscle activity of connecting a Heidbrink circle machine to the endotracheal tube of a patient anesthetized with nitrous oxide–oxygen and thiopental. Expiratory activity was increased, as shown by the rise of the electromyographic integral, and there was also a slight prolongation of inspiratory activity.

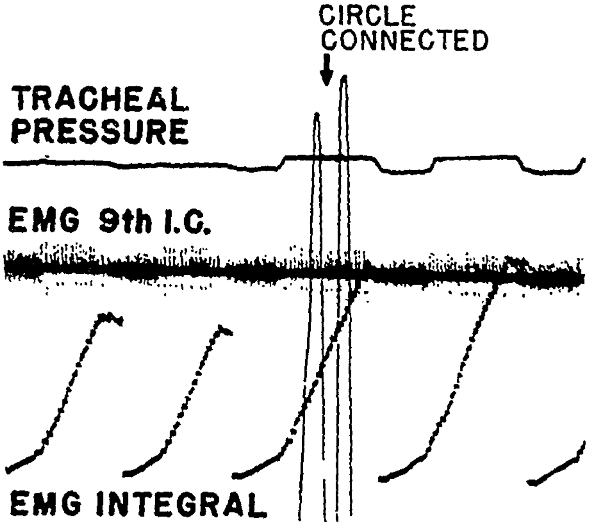

Fig. 6.—Ninth intercostal muscle activity during nitrous oxide–oxygen and thiopental anesthesia in man. At signal, circle machine was reconnected to endotracheal tube, resulting in increased fluctuations in intratracheal pressure *(upper trace)*, as well as prolongation of expiratory activity, shown by greater rise of electromyographic *(EMG)* integral *(bottom trace)*. There is also slight prolongation of inspiratory discharge.

Nitrous oxide is usually believed not to depress respiration,[3] although Seevers and Waters[4] have pointed out the dearth of quantitative observations concerning this gas and much of the early work on nitrous oxide anesthesia is vitiated by concomitant hypoxia. In our experiments, all the cats anesthetized with 80% nitrous oxide–oxygen (group 2) showed a diminished ability to inspire against an added resistance applied for a single breath. Arterial oxygen tensions were not measured, but, under the conditions of the experiment, any hypoxia would have been due to depression of ventilation by the anesthetic, since obstruction lasted for only one breath in each minute. The result would support the conclusion that nitrous oxide does, in fact, depress respiratory activity (fig. 4).

The stimulatory effect of light ether anesthesia on ventilation was observed in all the cats in group 3, chiefly as increased frequency of respiration, but, in spite of this stimulation, the animals' ability to overcome an inspiratory resistance was impaired (fig. 5) and the impairment became greater with each increase in the anesthetic vapor concentration.

From these experiments it appears that inspiratory resistance initially reduces the tidal volume and frequency of respiration and that the reduction in tidal volume is aggravated by pentobarbital, nitrous oxide, or ether anesthetic. If the flow resistance persists, there is a gradual recovery in the volume of ventilation, but even in the unanesthetized state this is not complete at the end of five minutes. This agrees with the findings of Zechman and co-workers [1] in man. Furthermore, the recovery rate is much slower during pentobarbital or ether anesthesia, indicating that the animal's compensatory mechanism was also disrupted to a certain extent.

Summary

The effect of added airway resistance on ventilation and respiratory muscular activity was studied in decerebrate cats before and during anesthesia. The ventilation was reduced with increased airway resistance in spite of augmented muscular activity.

The reduction of ventilation was proportional to the magnitude of the resistance. General anesthesia with pentobarbital, nitrous oxide, and ether aggravated this ventilatory disturbance; the impairment became progressively greater with deeper anesthesia.

MANUAL AND MECHANICAL CONTROL OF VENTILATION DURING CYCLOPROPANE ANESTHESIA

Mary R. Wester, M.D., LeRoy W. Krumperman, M.D., Esther M. Greisheimer, M.D.
and
James C. Erickson, M.D., Philadelphia

Respiratory factors that might be responsible for the appearance of cardiac arrhythmias during cyclopropane anesthesia were studied in 34 patients. Respiration was controlled manually in 15 cases and mechanically in 14; in 5 the control was manual in the beginning and mechanical later on. In the presence of such control, high blood levels of cyclopropane were quite compatible with adequate oxygenation as gauged by determinations of oxygen saturation, carbon dioxide tension, and pH. Electrocardiographic changes, interpreted as a shifting of the pacemaker toward the atrioventricular node, occurred repeatedly in five cases but were not associated with any noticeable cardiac irregularity. Distinctly palpable arrhythmias occurred in two patients; in one of these spontaneous respiration had been permitted early in the anesthesia and in the other there were indications of underlying cardiovascular instability. Under the conditions of this study hyperventilation was more frequent than hypoventilation. The evidence showed that cardiac arrhythmias perceptible by palpation should rarely occur when cyclopropane is administered with ventilatory control.

This study was undertaken originally to determine whether cardiac arrhythmias would occur consistently with cyclopropane anesthesia when respiration of the patient was controlled by the anesthetist. The respiratory depression usually caused by cyclopropane could be avoided by controlled ventilation. A comparison of manual and mechanical control of ventilation during anesthesia arose as an outgrowth of this study. Cyclopropane levels, oxygen content and capacity, carbon dioxide content and tension, and pH were determined in arterial blood prior to induction of anesthesia and at varying intervals during the course of surgery.

Materials and Methods

Thirty-four patients, ranging in age from 28 to 77 years, were selected at random for this study. With one exception, all underwent major intra-abdominal surgery. All but one were free from pulmonary symptoms and disease. Respiration was controlled manually in 15 cases and mechanically by a Jefferson ventilator in 14 cases; in five patients respiration was managed first by manual control and later by ventilator control. The electrocardiogram was monitored in 16 cases, and permanent tracings were made if any change in rate or pattern occurred. Control samples of arterial blood were drawn after

the patients had been breathing oxygen at a high flow (8-10 liters per minute) on a semiclosed system for 15 to 30 minutes. Anesthesia was induced by injection of a small amount of thiopental sodium, and endotracheal intubation was facilitated by administration of succinylcholine chloride. Cyclopropane anesthesia was begun immediately after intubation. When the Jefferson ventilator was being used, aliquots of gas from the inhalation stream were drawn at the time of arterial sampling and analyzed in a Scholander apparatus for percentage of oxygen in the inspired gas. This was compared with the percentage of oxygen flowing from the gas machine.

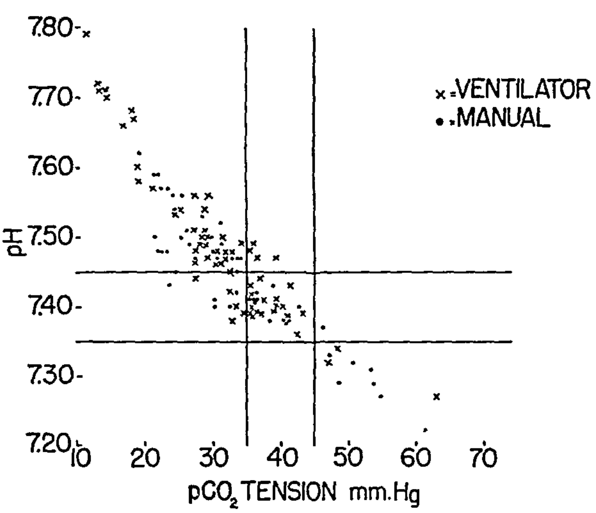

Fig. 1.—Incidence of hyperventilation and alkalosis with use of manually and mechanically controlled respiration during cyclopropane anesthesia.

Carbon dioxide and oxygen contents of arterial blood were determined on whole blood by the Van Slyke-Neill method,[1] modified for the presence of cyclopropane.[2] Cyclopropane level was determined by a method described previously.[3]

Results

In the majority of cases, there was a certain degree of hyperventilation with resultant alkalosis (fig. 1). This was more marked in the ventilator-controlled group. The carbon dioxide content of arterial blood decreased in each group but much more in the ventilator group. The mean carbon dioxide tension of plasma remained relatively steady in the manual and manual-ventilator groups but showed a pronounced drop in the ventilator group. Marked alkalosis (pH more than 7.55) was present in three cases when respiration was controlled manually and in five cases when ventilator control was used. Seven patients passed through periods of acidosis, but only two patients showed respiratory acidosis at the time of the last sampling. A graphic comparison of the findings in the manually controlled and the ventilator-controlled groups is shown in figure 2.

The control specimens of arterial blood were drawn after the patients had breathed 100% oxygen for 15 to 30 minutes. Despite this, the hemoglobin saturation with oxygen was frequently less than 100%. (Oxygen contents were corrected for oxygen dissolved in the plasma according to Comroe.[4]) The average control value was 97.3% saturation. Suboxygenation of control samples of arterial blood was apparently not the result of over-all hypoventilation, since plasma carbon dioxide tension was always within the normal range. It was more likely related to uneven alveolar ventilation and perfusion as the result of postural inactivity after premedication (fig. 3).

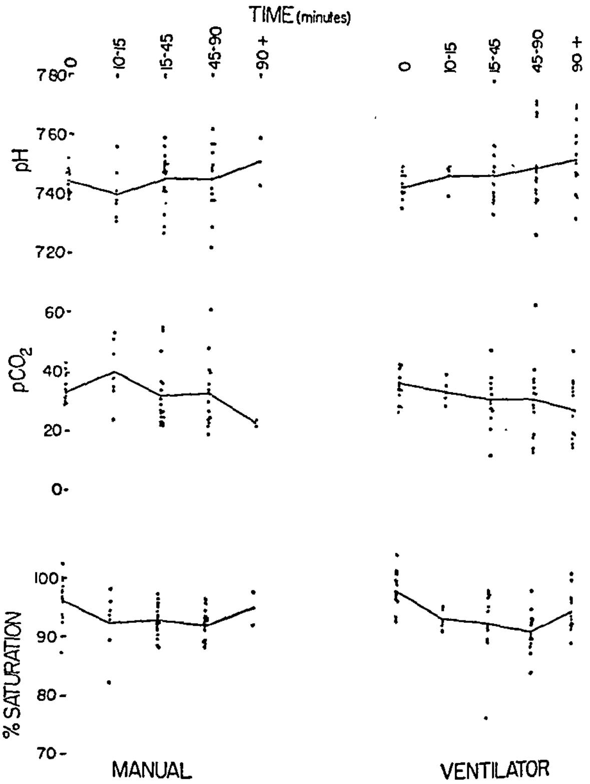

Fig. 2.—Comparison of findings in manually controlled and ventilator-controlled groups during cyclopropane anesthesia.

During cyclopropane anesthesia, the oxygen saturation tended to approach an average of 92% regardless of the type of ventilatory control. High blood levels of cyclopropane were not necessarily associated with poor oxygenation. In the latter part of our study, we determined the percentage of oxygen in the cyclopropane-oxygen mixture being delivered to the patient by the Scholander analysis.[5] As was expected, the oxygen concentration of the inspired gas was always less (average, 62.8%) than that calculated from the flow meter (average, 79.4%), since the inspired gas was diluted by recirculated gas from the rebreathing bag. When the Scholander analyses were carried out, the value for inspired oxygen concentration so obtained was used in correcting arterial oxygen content for dissolved oxygen in the plasma.

In 16 cases, the electrocardiogram was monitored and permanent tracings made at the time of arterial blood sampling. It was our original purpose to correlate the incidence of cardiac arrhythmias occurring during cyclopropane anesthesia with arterial blood levels of cyclopropane, oxygen, carbon dioxide tension, and pH. Assuming that arrhythmias might occur during deep anesthesia, we attempted to push anesthetic levels as deep as possible while monitoring the electrocardiogram for changes in rhythm. Respiration was controlled manually in eight cases and by the Jefferson ventilator in eight cases.

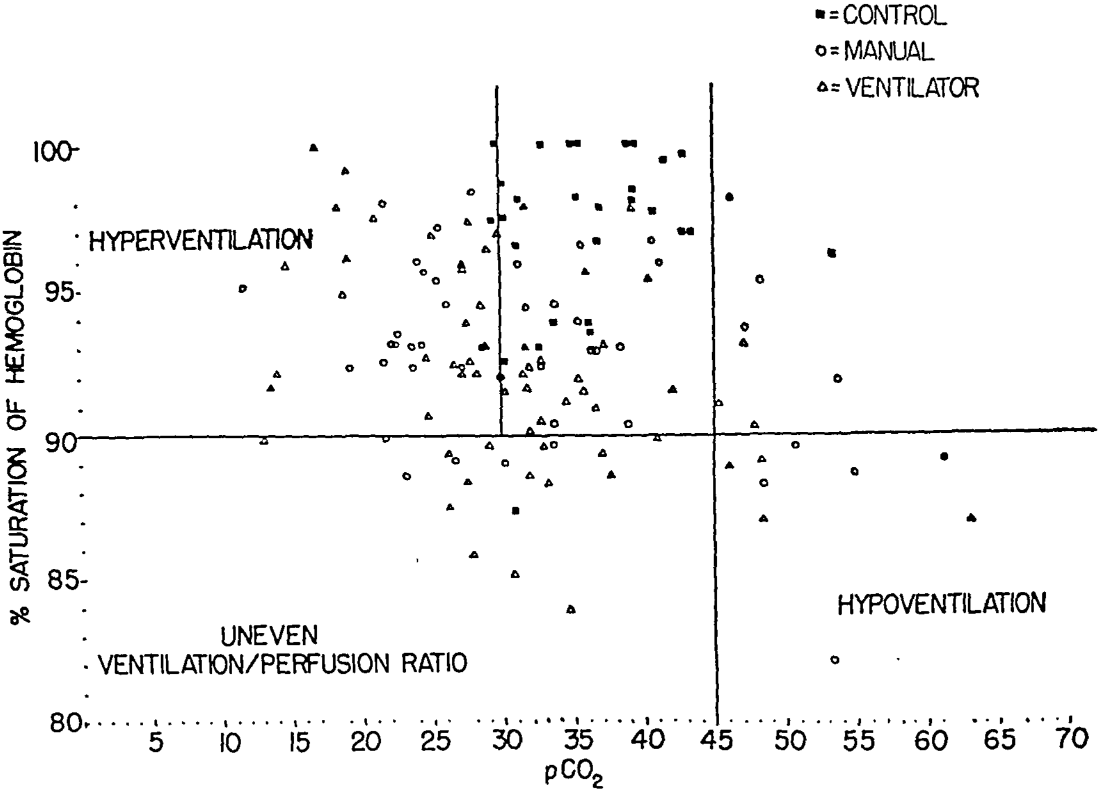

Fig. 3.—Ventilation and perfusion during cyclopropane anesthesia.

We found it impossible to provoke cardiac arrhythmias at will under these conditions when cyclopropane was administered by controlled ventilation. Deep anesthesia (cyclopropane level more than 15 mg. %) did not cause cardiac irregularities or consistent electrocardiographic changes, nor was light anesthesia a provocative agent.

The most common electrocardiographic alteration was an occasional shift of the cardiac pacemaker downward toward the atrioventricular node. This was unassociated with any noticeable cardiac irregularity and occurred repeatedly in five cases. It was unrelated to depth of anesthesia, although when it did occur lightening the anesthesia seemed to shift the pacemaker upward. There was a tendency for the arterial oxygen saturation to be moderately decreased at the time of the displaced pacemaker (89-92% saturation). Correlation with the clinical records of these five patients suggested that preexisting heart disease, momentary hypoxia or hypotension, or prior treatment with quinidine, digitalis, or thyroid extract contributed to the development of a wandering pacemaker during cyclopropane anesthesia.

In two cases distinctly palpable, potentially dangerous arrhythmias occurred. Frequent premature ventricular beats and bigeminy were noted on the electrocardiogram. One of these was the only case in which respiration was allowed to be spontaneous early in the anesthetic course, and respiratory acidosis (pH 7.29) together with moderately deep cyclopropane anesthesia existed at the time of the arrhythmia. Institution of manually controlled ventilation with return of the pH to 7.45 and slightly lighter anesthesia returned the electrocardiogram to normal. In the other case there was an unusually labile, elevated blood pressure. Arterial oxygenation was excellent throughout, and a constant respiratory alkalosis existed. The labile blood pressure and cardiac irregularity could not be explained. It might be assumed that delivery of oxygen to the myocardium was less than perfect.

Comment

Cyclopropane is a potent respiratory depressant, and its administration after that of preanesthetic drugs may result in hypoventilation, notably causing carbon dioxide retention, respiratory acidosis, and, occasionally, suboxygenation despite a high oxygen mixture. Control of respiration can be readily established either manually or mechanically, and respiratory acidosis can be avoided. Vigorous control of respiration will produce respiratory alkalosis by washing out carbon dioxide. We found overventilation to be more common than underventilation when artificial respiration was used.

The low carbon dioxide tension of respiratory alkalosis favors a more tenacious binding of oxygen and hemoglobin, whereas a high carbon dioxide tension favors dissociation of oxyhemoglobin.[6] We have not found clinical evidence that hyperventilation with respiratory alkalosis to the degree seen in these cases is harmful to the anesthetized patient. This corroborates the findings of other investigators.[7] The circulatory status of these patients was stable in most instances, and variations which did occur were apparently unrelated to respiratory control. Since carbon dioxide is a potent vasodilator, it has been suggested that coronary vasoconstriction may follow its decrease in the blood by hyperventilation.[8] In the present study, respiratory alkalosis was not associated with consistent electrocardiographic changes. If alkalosis was sufficient to produce coronary vasoconstriction, it was not so severe as to produce myocardial ischemia in the presence of the oxygen concentrations employed. Recovery from anesthesia was prompt in all cases, and there was no clinical evidence of cerebral impairment as a result of altered acid-base balance and cerebral circulation.

Despite hyperventilation sufficient to produce respiratory alkalosis, arterial blood oxygenation may be unexpectedly low because of uneven ventilation and perfusion of the lungs. In this study, when the inspired gas mixture contained 80% or more oxygen by the Scholander analysis, the uncorrected oxygen content of arterial blood was invariably greater than the oxygen capacity, indicating considerable oxygen dissolved in plasma. When the inspired oxygen concentration was 55% or less, the uncorrected oxygen content was less than the oxygen capacity, indicating hemoglobin unsaturation. Nahas and co-workers[9] showed that hemoglobin saturation was significantly less than 100% when healthy male subjects breathed 40, 50, and 60% oxygen. Our figures roughly corroborate these findings. Inspired gas oxygen concentration of 70% or more should yield arterial oxygen tensions of more than 400 mm. Hg; at this level uncorrected arterial oxygen content was usually higher than oxygen capacity.

Direct oxygen tension measurements in the presence of gaseous anesthetic agents are difficult and, as yet, not perfected. The most reliable means yet devised for determining relative difference in oxygen saturation at oxygen tensions more than 100 mm. Hg is by oximetry. The oxygen saturations calculated from the tonometric determinations of oxygen capacity give results which are about 2% below the values of oxygen saturation as determined by oximetry.[9]

Summary

Controlled ventilation during cyclopropane anesthesia by either manual or mechanical means usually produces hyperventilation and respiratory alkalosis. Oxygenation of arterial blood may be less than 100% even in the presence of hyperventilation if there is uneven ventilation and perfusion of the lungs. Cardiac arrhythmias perceptible by palpation rarely occur when cyclopropane is administered with ventilatory control. Downward displacement of the cardiac pacemaker as seen on the electrocardiogram may represent myocardial depression by cyclopropane superimposed on preexisting myocardial disease or drug therapy.

FACTORS TO BE CONSIDERED IN PLANNING A REHABILITATION SERVICE

Helen M. Wallace, M.D.
and
Frederic J. Kottke, M.D., Minneapolis

A rehabilitation service might reasonably be expected to carry out at least three functions: patient care, research, and training of professional personnel of all types. The advantages of location in a general hospital include the ready availability of all types of medical specialists and consultants; provision of both inpatient and outpatient care; avoidance of duplication of certain types of facilities; the possibility of earlier referral of patients; better dissemination of knowledge concerning rehabilitation; the possibility of the wider use of rehabilitation principles in the care of other patients within the general hospital; and the provision of surgical services in the same hospital in which the rehabilitation service is located. Unless a plan is made and carried through for the patient's continuing care and supervision, frequently he may receive little or no aftercare and may regress. Until more knowledge is available regarding primary prevention of many chronic diseases in both children and adults, rehabilitation services will be needed.

With the accumulation of new knowledge regarding techniques for the rehabilitation of patients with handicaps, many communities both in the United States and elsewhere are developing or planning to develop new "rehabilitation services." As with any relatively new field, there is agreement concerning some aspects of rehabilitation services and lively discussion about other aspects. Because in most communities there is a limitation of both funds and trained personnel, sound planning is essential in order that the available funds and personnel may serve the greatest number of patients most effectively. It is the intent of this paper to describe briefly some of the factors and principles to be considered in planning a rehabilitation service, as a guide for persons or for a community contemplating the development of such a service.

Functions and Location of a Rehabilitation Service

Functions.—A rehabilitation service might reasonably be expected to carry out at least three functions: 1. Patient care. This includes such phases as evaluation, diagnosis, treatment, vocational restoration, and continuing long-term care and supervision, on both an inpatient and outpatient basis. This primary function should include the evaluation of the results of the rehabilitation both of individual patients and of groups of patients. 2. Research. Especially to be noted is the area of experimentation with new methods and techniques of rehabilitation and of the evaluation of such experimentation. 3. Training of professional personnel of all types. This includes medical personnel (especially physiatrists, pediatricians, and internists), nurses (both hospital and public health), physical, occupational, and speech therapists, psychologists, vocational counselors, social workers, recreation workers, and others.

Location.—One of the controversial issues is that of location of the rehabilitation service. Possible locations include the development of (1) a rehabilitation service in a general hospital, (2) a rehabilitation service in a specialty hospital, such as that for orthopedic surgery, chronic disease, or otolaryngology, and (3) a completely separate rehabilitation "center." While we are in favor of the location of the rehabilitation service within the general hospital, we recognize that local circumstances may favor its development in another location.

The advantages of location in a general hospital include the ready availability of all types of medical specialists and consultants; provision of both inpatient and outpatient care; avoidance of duplication of certain types of facilities, such as laboratory or x-ray services; the possibility of earlier referral of patients in the general hospital for rehabilitation, because the rehabilitation service is an integral part of the general hospital; better dissemination of knowledge concerning rehabilitation to other members of the general hospital staff, both medical and nonmedical; the possibility of the wider use of rehabilitation principles in the care of other patients within the general hospital; the specific assignment of individual physicians from other services of the hospital, so that responsibility is fixed and so that there may be cross-fertilization of ideas regarding patient care; and the provision of surgical services in the same hospital in which the rehabilitation service is located, so that there may be some continuity of care prior to and immediately after the surgical phase.

From the University of Minnesota School of Public Health and the Department of Physical Medicine and Rehabilitation, University of Minnesota Medical School.

In the event that location within a general hospital is not possible, steps should be taken to assure the same quality of medical and health care as would be provided there. These steps include medical direction by a qualified physiatrist, preferably on a full-time basis; the provision, assignment, and easy availability of other medical specialists; a close working relationship with all other hospitals of the community, so that patients will be referred early to the rehabilitation service; when surgery is indicated, the working out of a careful plan with the surgical staff regarding timing, responsibility for joint supervision of the patient, continuity of care, and other factors; and provision of both inpatient and outpatient care and a unity system of records, so that continuity of care will be fostered. Also, a preferable location would be in a facility used for teaching purposes for the undergraduate and postgraduate training of professional personnel.

At the state level, thought should be given not only to planning for the rehabilitation service's location within the state capital or the central city but also to providing for regional or district rehabilitation services to meet the diagnostic, treatment, follow-up, and supervision needs on a long-term basis. This means, then, planning the services geographically so that they will be easily available to all citizens of the state on a regional or district basis.

A completely planned rehabilitation program must include local medical, nursing, social, and vocational counseling services to assist the handicapped patient in his return to normal community living. After the initial readjustment, some handicapped persons require little additional help. Others may need assistance and counseling for a long time before they achieve independence. The rehabilitation team in the local community can initiate the rehabilitation program for a handicapped patient early in the course of the disease, handle the entire rehabilitation program of the patient with less involvement, and be available to supervise and assist when the patient returns home again.

At the local level, other factors may warrant consideration in deciding on location. For example, the presence of a school for handicapped children, of a housing project with a fair number of handicapped people, or of a sheltered workshop may make it desirable to locate the rehabilitation service nearby for the convenience of these patients in order to reduce transportation costs and facilitate continuity of care.

Types of Patients

One of the basic decisions to be made is that regarding the types of patients to be cared for in the rehabilitation service. Is the service to be used for one or a few diagnostic types of patients, or is it to be used for all types of handicapped patients? On this basic decision will depend such essential aspects as the plan for the physical plant and staff. Both patterns have been used in the United States, and it is our opinion that, where a service is developed for patients with a variety of conditions, it is more likely to be of higher caliber, it can have a more complete staff, it is possible that the cost per patient will be lower because a reasonably complete staff can be provided, and more patients in the community are likely to be served. However, these are empirical observations, and objective studies of both methods are necessary.

Where a service is developed for one or a few diagnostic groups only, those patients included are likely to receive more concentrated care in a limited way. For example, the development of special separate services for patients with cerebral palsy has undoubtedly resulted in better care than previously existed; however, the provision of such separate services has usually meant that an ophthalmologist is rarely provided as a staff member of the cerebral palsy program. It has also meant that the hearing aspects of diagnostic and therapeutic care are frequently forgotten, overlooked, or, when provided, inadequate in quality. It is thought that the provision of a rehabilitation service for a larger number of diagnostic groups of patients will mean that all essential aspects of patient care will be considered for all patients.

In this connection, the question frequently is raised regarding the advisability of providing separate rehabilitation services for children and adults. Reasons advanced for the separation of children's services include the facts that children's needs are different and that the children's service may be of inferior quality because it may be overshadowed by the adult service. In our opinion, separation is unnecessary and may be undesirable because of the possibility of duplication of services and wastage of available funds and personnel. We believe that, if some program modifications can be made, it is more desirable to have the children's and adults' services together. These modifications include the need for staff understanding of the physical and emotional growth and development of children, the inclusion of a pediatrician on the staff, the provision of equipment of a size appropriate for children, consideration of children's educational and vocational needs, and the employment of a clinical psychologist who has had training and experience in working with children.

The Staff

There is general agreement that a multidisciplined staff is essential for a rehabilitation service. The composition of the staff to a certain extent is determined by the type of patients to be cared for. In a service caring for a wide variety of types of patients, personnel considered essential are as follows: the medical staff (especially the physiatrist, pediatrician for children, internist for adults, psychiatrist, ophthalmologist, orthopedic surgeon, cardiologist, surgeon, otologist, neurologist, and urologist); the nursing staff (staffs of both the institution and the community public health nursing agency); social service; dental and orthodontic service; therapists (physical, occupational, and speech); the psychologist: the vocational counselor; the audiologist; the recreation worker; technician services (laboratory, x-ray, electroencephalographic, and orthoptic); and the teacher.

It is evident that the list is long and that the cost of a reasonably complete service is high. The many facets of patient care—medical, social, psychological, educational, vocational, and recreational—must be considered together if the patient is to be assisted as a whole person. This means that the staff members must be provided with an opportunity and must be able to work together as a team or unit. If the team effort is not used, it may mean that the patient may be shunted from one staff member to another, timing of services may be incorrect, some available services may actually not be used for a patient, and the total essential needs of the patient and his family may not be considered.

One other aspect of the subject of the staff of the rehabilitation service merits discussion: direction of the service. There is general agreement that a full-time director is essential. Two patterns of directorship of rehabilitation services have developed in the United States: (1) the physician as full-time director and (2) a nonmedical staff member as full-time director, with the physician as full-time or part-time medical consultant. It is our opinion that the full-time director should be a physician—one who is interested and trained in the field of rehabilitation. Reasons for the need of a full-time medical director include the fact that there are primary medical and health needs of patients requiring rehabilitation which must be met and that, if the physical handicap can be eradicated or minimized, the vocational potential will be increased. Reasons advanced for the employment of nonmedical directors include the fact that it may be difficult to secure a physician on a full-time basis and that sometimes physicians are not as competent as administrators and are not as able to foster the carrying out of the team concept as other professional personnel. In any event, whichever plan is adopted, it is our belief that the full-time participation of at least one physician is essential and that the medical and health needs of the patient must receive careful consideration in addition to the patient's other needs—social, psychological, educational, vocational, and recreational.

The handicapped patient has been referred to the rehabilitation facility to undergo any intensive program of maximum restoration in order that he might return home as independent and self-sufficient as possible. The rehabilitation center, in planning for this goal, should include the family physician in the conferences and planning regarding the patient. From the family physician the center can obtain the record of the patient's previous health. When the patient has completed his rehabilitation program he will return home and again be cared for by his family physician. If the family physician participates with the rehabilitation team during the rehabilitation program, he has a better understanding of the patient, his problems, and his potential and is better prepared to resume his care when he returns home.

The Program

While it is impossible in this paper to discuss all aspects of the program, certain areas of significance will be selected. It would be expected that each patient would be evaluated by the team on admission to the rehabilitation service, either as outpatient or as inpatient, and that the team members would discuss and make a plan for the patient. It would be expected that some one team member would be selected to interpret carefully the findings and recommended plan to the patient, his family, or both. Furthermore, it would be expected that the patient would be periodically reevaluated, perhaps every three to six months, in order that his program may be modified as indicated by his condition; this should apply to patients within the inpatient as well as the outpatient service. The reasons for periodic reevaluation of patients include the necessity of changing the program as the patients' needs change and the importance of a concerted effort to reduce unnecessary inpatient care when it is no longer warranted by the patients' condition, with its resultant reduction in patient costs and freeing of facilities for other patients.

Several methods exist for team functioning; included are the periodic team staff conference and the periodic team rounds. The former is usually conducted weekly and the latter daily but on a more abbreviated basis. All staff members attend and participate in the weekly staff conference, when, usually, service problems are discussed, policy decisions made, and certain patients reviewed (new admissions, those considered for discharge, those due for periodic review, and those with special problems). Many of the staff members attend daily rounds when the majority of patients are reviewed.

Surveys have indicated the importance of integrating the instruction given to patients in the various therapy departments with their activities during he rest of the day on the inpatient service. For example, if a patient is learning ambulation in the physical therapy unit, he should be given assistance and an opportunity to continue this when he is back in the floor nursing unit. This same principle applies to many other patient activities—dressing, toilet care, feeding, speech, tooth brushing, and others. In order to facilitate this, personnel employed in the floor nursing unit (nurses, attendants, and orderlies) must have reasonably good general technical skills and must have an intimate knowledge of the therapy program for each patient. It also implies a fundamental shift in concept of patient care on the part of personnel employed in the floor nursing unit from that of passive bed care to that of the patient's active participation in his own care.

Another aspect is integration of the vocational program with the other aspects of patient care—medical and health, social, psychological, and educational. This means that a vocational counselor will be an integral part of the staff of the rehabilitation service, actively participating in patient care with all teen-aged youths and adults known to the service. It also means that, whenever possible, the various steps of testing, guidance, training, and placement, as well as the sheltered workshop, should be a part of the rehabilitation service. Where the vocational aspects have not been so integrated, several undesirable results in patient care may occur—either there may be delay in referral of patients to the vocational agency or the vocational agency may be placed in the position of attempting to do testing, guidance, training, and placement without an adequate knowledge of the patient's physical and mental condition and capacity.

Patient records are essential, not so much in themselves but because they represent the one tangible source of description of the patient's course and response to the rehabilitation process, in contrast to dependence on man's memory and changing personnel. Thus, the patient's record should give a reasonably complete picture of himself and his family on admission, throughout his course, and at the time of separation from the service. The record should contain not only the medical and health data but also information regarding the patient's social, psychological, educational, and vocational status—both on an inpatient and on an outpatient basis. The data should be collected in a uniform manner on all patients, so that results in patient care may be analyzed.

Physical Plant

Special features of the physical plant include the floor nursing unit with nonskid floors, special bathroom facilities for easy wheel chair-to-toilet transfer, special kitchen facilities for teaching self-help, and service areas to be used jointly by the inpatient and outpatient services, including physical therapy, occupational therapy, speech therapy, psychological testing, and the vocational assistance areas with the sheltered workshop, in addition to offices for key personnel.

Ramps are considered essential where there is a change of floor elevation. Special unloading and reception areas for transportation vehicles are helpful. Where teachers are provided for children on inpatient services, classrooms are necessary.

Continuing Care of the Patient

Discharge planning and arrangements are an important step in the patient's rehabilitation. They include consideration of the family attitude, home conditions, details of the patient's continuing care and supervision, education of patients of school age, vocational guidance of youth and adults, and transportation. This discharge planning, to be effective, cannot take place only at the time of discharge. It must occur early and throughout the patient's rehabilitation course by maintaining close contact with the family, helping the family to accept the patient back into their family unit, assisting them with planning the details of the patient's 24-hour care at home if homebound, and planning facilities and equipment for such items as toilet care, wheel chair activities, and bathing. Frequently, both the social worker and the public health nurse play key roles, the former by close family contact within the rehabilitation service and the latter by working with the family at home. One of the crucial periods in the home care of the homebound patient is the first few days after the patient's discharge from the inpatient service—from the viewpoint of both the patient and his family. This particular period of stress is when some extra guidance and supportive services can be of great assistance until the adjustment within the home is made.

Unless a plan is made and carried through for the patient's continuing care and supervision, frequently he may receive little or no care and will regress. For this reason, details of the plan should be worked out prior to discharge and then carefully interpreted to the patient and his family. Periodic close supervision for the patient who is moderately to severely handicapped is essential. For the homebound patient, many communities have now worked out organized home care programs whereby the team of services is brought to the patient at home as he needs them. Organized home care programs have stemmed from a hospital, a medical school, a voluntary public health nursing agency, and a health department; it seems likely that they might stem from a rehabilitation service as well.

For the handicapped patient with a vocational potential, vocational evaluation and planning should be begun early in his rehabilitation program. In addition to psychological testing, prevocational evaluation may be desirable prior to placement in a vocational school or on the job. Many severely handicapped persons have had no work experience or have not been employed for many months. Their living habits are unsuitable for the demands of an occupation. A prevocational evaluation unit can provide a practical situation to check punctuality, personal cleanliness and neatness, ability to work with and tolerate others, speed and carefulness in work, and maintenance of interest in work. In the prevocational evaluation clinic, the level of ability of the patient can be established. The vocational counselor who has had an opportunity to work with a patient in his prevocational evaluation can place him with assurance of his level of performance.

Vocational placement of handicapped persons is usually a stressful situation. Most employers have some reservations about a handicapped employee. Plant physicians feel the personal insecurity that in accepting a handicapped employee they may be open to criticism if an accident occurs. Agents for workmen's compensation insurance generally warn employers that they may be incurring increased risks and rates if they employ handicapped persons, even though all available statistics are contrary to this opinion. For this reason, the vocational counselor who makes the placement must make follow-up calls and visits to the employer and employee to see that the adjustment to the job and the performance of the job are satisfactory. For the employable patient, successful employment is the goal. None of the rehabilitation team, physician, therapist, counselor, or agency, can consider that a successful job of rehabilitation has been accomplished until the patient is satisfactorily employed.

Relationship to Other Community Agencies

On a cooperative basis, a rehabilitation service can carry out some other significant community functions. For example, in the case of adults, it can provide evaluation and diagnostic work for all patients applying for public assistance under the aid-to-the-disabled category and it can include in its rehabilitation program those patients found able to be rehabilitated. It can provide a similar service for youth and adults applying for vocational assistance under the state official vocational rehabilitation program. These two steps alone would mean earlier and more complete patient care with better results—and probably a considerable saving in tax funds. Similarly, the rehabilitation service can work cooperatively with the official crippled children's agency in reviewing the status of applicants for inpatient care and for special educational placement, such as home instruction, special schools, and special classes.

As public health programs begin to accept their responsibility in the chronic disease field, the need for public health personnel to receive training in this field will become more apparent. Here, too, the rehabilitation service is in a strategic position because of the training it can provide for health officers, public health nurses, nutritionists, and health educators.

Summary

A rehabilitation service should be located in a general hospital and care for many types of handicapped patients rather than limit the service to one or a few diagnostic groups. A full-time director, preferably a physiatrist, is desirable. Some aspects of the program include staff rounds and conferences, integration of therapy activities with the rest of the patients' care, integration of the vocational aspects into the other facets of rehabilitation, and recording of data. Continued care after discharge from the inpatient program is important.

Until more knowledge is available regarding primary prevention of many chronic diseases in both children and adults, rehabilitation services will be needed. The ultimate role which a rehabilitation service plays in the care of patients in a community will depend to a large extent on the soundness of the original planning and the staff's and community's concept of what it has to offer. Some of its role is also dependent on adequate financial support from the community, especially for the employment of the many kinds of professional personnel necessary in rehabilitation of patients.

CLINICAL NOTES

CYTOMETER CHAMBER SPERMATOCIDAL TEST

AN IMPROVED TECHNIQUE FOR EVALUATING SPERMATOCIDAL ACTIVITY

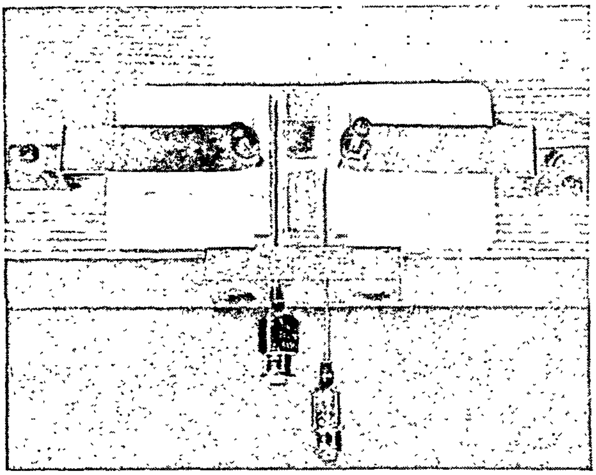
Dicran A. Berberian, M.D., Loudonville, N. Y.
and
Ralph G. Slighter, A.B., Rensselaer, N. Y.

Tests which measure the time required for varying concentrations of test substances to completely immobilize all spermatozoa in a given volume of spermatic fluid have been used in evaluating the relative spermatocidal activity of these substances.[1] Such dilutions are useful for measuring the intrinsic potency of an active ingredient in terms of minimal spermatocidal concentration, but the degree of homogenization required to provide reproducible results has no counterpart in coitus, and the relatively high values obtained are not applicable to defining the spermatocidal activity of contraceptive gels under conditions of use.

In order to approach normal conditions Gamble[2] devised a "diffusion test" for evaluating the spermatocidal activity of undiluted contraceptive products. The Gamble procedure utilizes glass tubing 2 cm. in length with an internal diameter of 2 mm. in which a column of semen is brought into contact with a column of undiluted contraceptive jelly, cream, or suppository mass. The observer measures the *time required at 37 C for immobilization of* spermatozoa in the sperm column as a result of diffusion of the active ingredients. The relatively small interface and long columns of materials result in prolongation of the time required for complete immobilization.

From the Research Laboratories of Esta Medical Laboratories, Inc., Rensselaer, N. Y.

The diffusion procedure has been usefully modified by use of a Spencer "Bright-Line" hemacytometer instead of a capillary tube, with resultant reduction of time required for immobilization and a gain in reproducibility. The test procedure is described below, and the results are compared with those obtained by the capillary tube method in tests conducted concurrently on the same samples of semen and spermatocides. The test procedure was greatly facilitated by use of a newly devised cytometer holder, which is described.



Hemacytometer and cover glass secured in holding device. Needles inserted into lateral moats through holes in brass template for purpose of orientation.

Materials and Method

The Spencer "Bright Line" hemacytometers, with improved double chamber and cover glasses, were used. The platforms of the six chambers used in this study varied from 6.0 to 6.2 mm. in width and were separated from each other by a moat 3.1 to 3.6 mm. wide. The cover glasses measured 19.1 to 19.8 mm. in width; hence, the length of platform covered was within that range, less the width of the moat. When the space between the platform and cover glass was filled with semen and the moats were filled with a spermatocidal preparation, the interface available for diffusion was 44 to 44.8 mm. in length by 0.1 mm. in depth, or 4.4 to 4.48 sq. mm. in area. The total volume of semen under observation was approximately 4.8 cu. mm.

Displacement of the cytometer cover glass during filling of the moats was avoided by use of the holding device illustrated in the figure. The holder consists of a wooden block equipped with a pair of adjustable spring clamps so spaced as to provide a downward thrust of the screws to hold the cover glass firmly in position when the cytometer is in place. The front of the block is provided with a brass template, 37 by 19 by 6 mm., through which holes have been drilled. These holes just permit passage of a 22-gauge hypodermic needle into each of the lateral moats of a cytometer slide. This device supports and guides the needle without risk of accidental displacement and facilitates uniform distribution of the injection mass.

Test Procedure.—The cover glass is held firmly in position and semen is run onto the open ends of the platforms until the areas under the cover glass are completely filled without overflow. The barrel of a tuberculin syringe fitted with a 22-gauge straight needle is filled with the spermatocidal preparation. The needle is then inserted through the brass template into one lateral moat, and the area of the moat under the cover glass is filled as the needle is slowly withdrawn along the moat until the transverse moat is reached. The needle is halted at the open edge of the transverse moat with the needle opening directed toward the moat and the material is extruded until the transverse moat is completely filled; the remaining portion of the lateral moat is then filled as the needle is slowly withdrawn. The other lateral moat is completely filled with the test material in the same manner. Both ends of the cover glass and the ends of both lateral moats are sealed with petrolatum jelly to prevent concentration by evaporation. Microscopic examination for evidence of motility of spermatozoa is started as soon as the preparation is completed and is continued at frequent intervals. Spermatocidal time is recorded as the time from the filling of the moats with the contraceptive material until all spermatozoa under the cover glass, in both chambers, have been immobilized at room temperature (74 to 78 F).

Gamble's capillary tube diffusion test and the cytometer chamber test procedure were used concurrently to determine the spermatocidal times of several commonly used contraceptive products and a new formulation (Lanesta gel) designed for the same purpose. The products in the accompanying table are listed in increasing order of their respective mean spermatocidal times. Spermatic fluids were provided by six young healthy donors aged 23 to 37 years. Ejaculates were submitted early in the morning and used within one to four hours of submission. On any one day only one specimen of spermatic fluid was usually used, as from one to four tests were run on each contraceptive preparation. Several samples of spermatic fluid were obtained from each donor over a period of weeks. Inasmuch as specimens differed from source to source and even ejaculates from the same donor were not always comparable in respect to percent-

In Vitro Spermatocidal Activity of Six Contraceptive Jellies

† Lanesta gel.

age of viability and degree of motility of spermatozoa, each specimen of spermatic fluid was tested at the same time by both methods and against each preparation in order to compensate for differences which might result from the testing of different ejaculates. Each contraceptive was tested as many as 28 to 50 times by the cytometer chamber procedure and 28 to 61 times by Gamble's capillary tube diffusion procedure.

Results.—By the cytometer chamber diffusion test the new spermatocidal formulation, jelly A (Lanesta gel), immobilized spermatozoa in one-third the time required for any of the three other most active products (jellies B, C, and D), and in one-fifth the time required for jelly E and in one-eighth the time required for jelly F. The absolute figures for each are given in the table in terms of mean spermatocidal times. By Gamble's capillary tube test, jelly A demonstrated a correspondingly wide margin of superiority over the other products tested.

Comment

The use of procedures for measurement of spermatocidal time which involve dilution and/or mixture of contraceptive with spermatic fluid is unsatisfactory because neither the required degree of mixing nor the extent of dilution has any counterpart under conditions of use. Moreover, reproducibility is difficult to achieve in tests which require mixing but do not require dilution. In Davidson's test[3] spermatozoa cannot be readily seen except in certain irregular areas, because of the opacity of some preparations; also this test requires the use of nonviscous semen. By the Sander-Cramer[4] and Millman[5] saturation tests, the time element for mixing of jelly and semen, preparation of slide, and examination of several fields under the microscope is so short (20 seconds) that duplication of test results is difficult and subject to wide variation. In addition, these tests often require several milliliters of semen per test, depending on the activity of the preparation. Thus, repetition of the test and simultaneous comparison with other preparations using the same ejaculate is seldom possible. The authors of these tests recommend the use of nonviscous spermatic fluid and admit that results are not always reproducible with "sticky" samples. Millman's "zone" test[5] claims to measure the penetration of spermatozoa into the contraceptive preparation. Gamble[2] pointed out in discussing Millman's procedure that the high dilutions used in the zone test and the short distances traversed by spermatozoa indicate that penetration into undiluted jelly or cream is nonexistent or minimal. By direct methods of observation, such as the present cytometer chamber spermatocidal test method, in which it is possible to observe every single spermatozoon in the preparation, we have never observed active penetration of spermatozoa into any undiluted contraceptive.

There is no factual basis for the assumption that there is any marked degree of dilution of a contraceptive in the vagina by vaginal secretions. The average volume of vaginal secretion after copulation was postulated[1] to be approximately 1 ml., whereas the usual volume of contraceptive jelly or cream that is introduced into the vagina is 5 ml.; therefore the greatest possible source of dilution is seminal fluid, which rarely exceeds 5 to 7 ml. Under these conditions, dilution of jelly or cream is likely to be 1:1 or maximally 1:2. Also, contraceptive preparations are characteristically either hydrophobic, because of fatty ingredients in the formula, or they are gelled with gums which are not readily miscible and which require time for imbibition of water. In view of the fact that spermatozoa cannot be depended on to actively penetrate into a jelly or cream, the best alternative to thorough mixing by artificial methods is dependence on diffusion of spermatocidal constituents into the spermatic fluid. The cytometer diffusion procedure described herein offers a convenient, reproducible method of measuring this diffusibility and of predicting the clinical effectiveness of a contraceptive jelly, cream, or suppository mass.

Summary

A new test procedure, designated the cytometer chamber spermatocidal test, for determining the speed of spermatocidal action of contraceptive products is a modification of Gamble's diffusion test, with use of a double chamber hemacytometer instead of capillary tubes.

The new test procedure is simple to carry out. The range of variations from one test to another falls within narrower limits than the Gamble diffusion test. The over-all time required for spermatocidal action is shorter by the new procedure than by the Gamble test.

A new contraceptive formulation was found to immobilize human spermatozoa in one-third to one-eighth the time required by five of the leading contraceptive products currently available.

389 Loudonville Rd. (Dr. Berberian).

Mr. K. T. Krantz helped to devise the cytometer holder.

CLINICAL EVALUATION OF THE STARCH TOLERANCE TEST

F. Warren Nugent, M.D.
and
William A. Millhon, M.D., Boston

Early diagnosis of chronic benign or malignant disease of the pancreas is a problem that has haunted physicians for many years. In spite of rather startling advances made in other fields, clinical evaluation and a high index of suspicion continue to be the mainstays in the diagnosis of these diseases. Several new laboratory tests or modifications of older tests have been put to trial, the starch tolerance test described by Althausen and Uyeyama[1] being one of these. We have attempted to evaluate this test clinically.

The starch tolerance test is based on the premise that pancreatic amylase is the only significant physiologic enzyme responsible for the breakdown of starch into disaccharides. In this form it is absorbed by the intestinal tract. The original authors found that 87% of all patients with chronic benign and malignant disease of the pancreas showed abnormal results on starch tolerance tests. Kalser and coworkers[2] in evaluating the starch tolerance test found an accuracy of 69% in proved cases of pancreatic disease. With these facts in mind we felt that the test should be evaluated with regard to its relative merit in the diagnosis of pancreatic disease.

Materials and Methods

Sixty-eight patients were studied in the department of gastroenterology at the Lahey Clinic. In all cases pancreatic disease was suspected clinically. Studies included history, physical examination, routine laboratory tests, gastrointestinal x-rays, and such further studies as were deemed necessary for their clinical evaluation.

All patients were given a starch tolerance test by the method of Althausen and Uyeyama, with use of either United States Pharmacopia corn starch or chemical "soluble starch." In all cases the starch was prepared under the supervision of one of us (F. W. N.). This was done because of the known difficulty in preparation and also to encourage rapid ingestion by the patients of this distasteful mixture. Although saccharin and small amounts of lemon juice were used, we were unable to produce a palatable mixture.

The maximal rise in blood sugar level after the oral ingestion of glucose was compared to the rise after oral ingestion of starch and calculated as suggested by the original authors. All results over 100% were considered abnormal, while those under 100% were accepted as being within the normal range.

Results

Of the 68 cases studied, in 50 (cases 1-50) the *final diagnosis was some condition other than pancreatic disease*. These conditions included functional disease of the gastrointestinal tract, infectious hepatitis, duodenal ulcer, gastric ulcer, cholelithiasis, retroperitoneal malignant disease not originating in the pancreas, renal cysts and neoplasms, malabsorption syndrome, segmental jejunitis, and hiatus hernia.

In 46 of these cases, the starch tolerance test gave negative results, and in 4 the results were positive. One patient (see table, case 45) had proved metastatic malignancy in a lymph node; this obstructed the ampulla of Vater and therefore the test results cannot be considered false-positive. The results in the other three cases, however, must be considered false-positive. One patient (case 44) had infectious hepatitis, but exploration for suspected carcinoma of the head of the pancreas revealed a normal pancreas. Three other patients with infectious hepatitis had negative results on starch tolerance tests. In one patient (case 24), the absorption of glucose was early and rapid. Within the first half-hour the blood sugar level rose 119 mg. per 100 cc. after ingestion of glucose, whereas it rose only 29 mg. per 100 cc. in a similar period after ingestion of starch. This probably explains the false-positive test. This patient was seen two years later and showed no clinical evidence of pancreatic disease. The other patient (case 29) had cholelithiasis and results of the test were false-positive.

Twelve patients (cases 57-68) had chronic relapsing pancreatitis, as proved at surgical exploration. The starch tolerance test gave positive results in eight of these cases; in four the results were negative. Thus, in cases of chronic benign disease of the pancreas, the over-all accuracy was 66.6%. The glucose tolerance test showed positive results in seven of these cases (58.3%).

From the Department of Gastroenterology, Lahey Clinic. Dr. Millhon is a Fellow in Gastroenterology.

Six cases of carcinoma of the pancreas are included in the group (cases 51-56). The presence of carcinoma was proved at operation in all these cases. In only one case (case 55) did the starch tolerance test show positive results, while in the other five the results were within normal range. The glucose tolerance test showed positive results in five (83.3%). Two other patients (cases 48 and 49) had the picture of carcinoma of the pancreas clinically and roentgenologically. Lung metastases were present in one and metastases to the supraclavicular lymph nodes in the other. Neither was included among the group of patients with cancer of the pancreas, since the diagnosis was not proved. The starch tolerance test gave negative results in both instances.

Summary of Results in Sixty-Eight Patients Given Starch Tolerance Test

Case, No.	Final Diagnosis	Starch Test, %	Remarks
1	Functional gastrointestinal disease	32	Abdominal pain
2	Functional gastrointestinal disease	2	Abdominal pain
3	Functional gastrointestinal disease	0	Abdominal pain and vomiting
4	Functional gastrointestinal disease	0	Abdominal pain and diarrhea; latent diabetes
5	Functional gastrointestinal disease	37	Healed pyloric ulcer and gallstones; latent diabetes
6	Functional gastrointestinal disease	0	Abdominal pain
7	Functional gastrointestinal disease	73	Abdominal pain
8	Functional gastrointestinal disease	9	Abdominal pain
9	Functional gastrointestinal disease	54	Pain in left side of chest; ? enlargement in head of pancreas on x-ray
10	Functional gastrointestinal disease	3	Abdominal pain
11	Functional gastrointestinal disease	0	Abdominal pain; latent diabetes
12	Functional gastrointestinal disease	0	Abdominal pain
13	Functional gastrointestinal disease	0	Abdominal pain
14	Functional gastrointestinal disease	2	Abdominal pain
15	Functional gastrointestinal disease	0	Abdominal pain
16	Functional gastrointestinal disease	0	Back pain; weight loss
17	Functional gastrointestinal disease	0	Abdominal pain; latent diabetes
18	Functional gastrointestinal disease	27	Abdominal pain
19	Functional gastrointestinal disease	0	Weakness; weight loss
20	Functional gastrointestinal disease	32	Abdominal pain; latent diabetes
21	Functional gastrointestinal disease	60	Abdominal pain; nausea
22	Functional gastrointestinal disease	74	Healed gastric ulcer; abdominal pain; latent diabetes
23	Functional gastrointestinal disease	40	Abdominal pain; latent diabetes
24	Functional gastrointestinal disease	310	Abdominal pain; rapid absorption of glucose
25	Cholelithiasis	1	Abdominal pain
26	Cholelithiasis	69	Weight loss; anorexia
27	Common duct stone	0	Abdominal pain
28	Common duct stone	21	Abdominal pain; latent diabetes
29	Cholelithiasis	138	Abdominal pain; latent diabetes
30	Cholelithiasis	54	Abdominal pain
31	Segmental jejunitis	63	Abdominal pain; segmental jejunitis on x-ray; latent diabetes
32	Intermittent obstruction of small intestine	0	Abdominal pain
33	Hiatus hernia	72	Abdominal pain; latent diabetes
34	Hiatus hernia with regurgitation; esophagitis	52	Regurgitation and vomiting; weight loss
35	Duodenal ulcer	0	Abdominal pain
36	Duodenal ulcer	0	Abdominal pain
37	Duodenal ulcer	0	Right upper quadrant pain
38	Left renal cyst	0	Midabdominal pain
39	Left renal cyst	0	Abdominal pain; abdominal mass on left side; latent diabetes
40	Malabsorption syndrome	60	Diarrhea of 18 months' duration
41	Hepatitis	97	Abdominal pain; jaundice; diabetes mellitus
42	Infectious hepatitis	66	Jaundice; x-ray—question of enlargement of head of pancreas; latent diabetes
43	Gastric ulcer; hepatitis	0	Abdominal pain; diarrhea; latent diabetes
44	Hepatitis	559	Vomiting with weight loss; latent diabetes
45	Metastatic carcinoma of colon	139	Mass involving duodenal area and invading ampulla of Vater; latent diabetes
46	Malignant melanoma	0	Retroperitoneal involvement with metastasis to liver; latent diabetes
47	Adenocarcinoma of bile ducts	11	Abdominal pain
48	Retroperitoneal malignancy with metastasis to lungs	29	Abdominal pain; latent diabetes; mass located in pancreatic area, probably representing pancreatic carcinoma but not proved
49	Metastatic malignancy	0	Abdominal pain; latent diabetes; x-ray evidence of mass in pancreatic area, scalenus node positive for carcinoma
50	Carcinoma of the left kidney	30	Weight loss; anorexia
51	Carcinoma of the pancreas	9	Back pain; weight loss; latent diabetes
52	Carcinoma of the pancreas	36	Abdominal pain; latent diabetes
53	Carcinoma of the pancreas	14	Abdominal pain; weight loss; latent diabetes
54	Carcinoma of the pancreas	0	Abdominal pain
55	Carcinoma of the pancreas	100	Abdominal pain; latent diabetes
56	Carcinoma of the pancreas	0	Right upper quadrant pain; anorexia; diabetes mellitus
57	Chronic relapsing pancreatitis	0	Abdominal pain; weight loss; latent diabetes; pancreatic calcifications
58	Chronic relapsing pancreatitis	91	Abdominal pain; latent diabetes; pancreatic calcifications
59	Chronic relapsing pancreatitis	35	Abdominal pain; vomiting; latent diabetes; pancreatic calcifications
60	Chronic relapsing pancreatitis	226	Abdominal pain
61	Chronic relapsing pancreatitis	0	Abdominal pain; vomiting
62	Chronic relapsing pancreatitis	1,850	Abdominal pain; pancreatic cyst
63	Chronic relapsing pancreatitis	200	Abdominal pain; nausea; vomiting
64	Chronic relapsing pancreatitis	140	Abdominal pain; fever
65	Chronic relapsing pancreatitis	173	Abdominal pain; latent diabetes
66	Chronic relapsing pancreatitis	Inf.	Abdominal pain; latent diabetes
67	Chronic relapsing pancreatitis	105	Abdominal pain; latent diabetes
68	Chronic relapsing pancreatitis	165	Abdominal pain; latent diabetes

In all, 18 of the 68 patients in the series proved to have pancreatic disease. In only nine of these cases did the starch tolerance test show positive results. Thus, the over-all accuracy was only 50%. In three instances the test results were false-positive.

Of the 68 patients, 30 had latent diabetes. This condition was defined in our study by a blood sugar level exceeding 140 mg. per 100 cc. two hours after ingestion of glucose. In 12 (66%) of the 18 proved cases of pancreatic disease, latent diabetes was also present. In the 50 patients who did not have pancreatic disease, 18 (36%) had latent diabetes, including 3 of the 4 patients with infectious hepatitis.

In all patients with pancreatic disease, multiple abdominal roentgenograms were taken; these were carefully studied for evidence of calcification in the pancreatic area. Of the 12 patients with chronic relapsing pancreatitis, calcification was found in three instances. Calcification was not noted in any of the six cases of carcinoma of the pancreas.

Comment

The pancreas has two major physiological functions: the endocrine and the exocrine. The endocrine function can be assessed fairly accurately by the glucose tolerance test, a well-established method. Tests of exocrine function, unfortunately, are not as accurate. These can be roughly divided into two groups: tests of acinar function and tests of ductal cell function. Excretion of bicarbonate and water by the ductal cells is the basis of the secretin test.[3] Acinar function is determined by the enzymatic secretions reaching the blood or small intestine. Amylase and lipase determinations, the gelatin tolerance test,[4] the starch tolerance test, radioactive-labeled protein[5] and radioactive-labeled fat[6] studies all attempt to evaluate this function.

Normal pancreatic exocrine function is, of course, a combination of these actions. Acinar cells must be present to secrete the enzymes and a patent ductal system is necessary to deliver them to the intestine. It is well known that the pancreas has a tremendous reserve capacity and that a large portion of the gland may be destroyed without producing significant abnormality in the over-all pancreatic function.

The starch tolerance test is based on a comparison of the ability to absorb orally administered glucose to the ability to absorb orally administered starch. This, in turn, is based on the theory that pancreatic amylase is the only physiologic substance capable of hydrolyzing starch in significant amounts.

Salivary amylase, gastric hydrochloric acid, hydrolyzing substances secreted by the small intestine, and bacterial fermentation in the intestine are capable of producing degrees of starch hydrolysis. That these factors can influence this test is well attested to by the case of Kalser and co-workers.[2] In this case a patient who had undergone total pancreatectomy showed an elevation of the blood sugar level from 200 mg. per 100 cc. to 422 mg. per 100 cc. after the ingestion of starch.

The transit time of food from stomach to colon (particularly for cases in which segments of the upper gastrointestinal tract have been resected) and malabsorption or unusually rapid absorption of glucose can obviously be modifying factors.

Our results with this test would indeed seem discouraging. In all instances, proved pancreatic disease was strongly suspected preoperatively on the basis of evaluation of the clinical course, glucose tolerance, roentgenographic findings, and other evidence. In no case was the starch tolerance test instrumental in solving the problem.

In one patient (case 57) the duct of Wirsung was completely obstructed by a calculus 3 cm. distal to the ampulla of Vater, yet the starch tolerance test gave negative results. In another patient (case 62), however, with cyst formation and pancreatitis localized to the tail of the pancreas, the starch tolerance test gave strongly positive results in spite of the fact that the proximal two-thirds of the gland was quite normal.

The most disturbing aspect of this study is its failure to provide a means of diagnosing carcinoma of the pancreas. This is one of the most difficult challenges we must face. Despite the fact that in each of our six cases the diagnosis was strongly suspected clinically, only one patient showed positive results on the starch tolerance test.

Certainly all efforts must be directed to the search for means of early diagnosis of pancreatic disease. We do not feel, however, that the starch tolerance test is the answer.

Summary

The starch tolerance test was performed on 68 patients in whom pancreatic disease was suspected. Of the 18 patients with proved disease, 9 (50%) had positive results on the starch tolerance tests. Only one patient with proved carcinoma of the pancreas showed positive results on starch tolerance test, whereas the results were negative in the other five. We do not believe this is a reliable test for the detection of pancreatic disease, on the basis of the studies described in this report.

CORNEAL COMPLICATION OF CHLOROQUINE (ARALEN) PHOSPHATE THERAPY

Robert W. Zeller, M.D.
and
Donald Deering, M.D., Portland, Ore.

Alteration of the corneal epithelium causing blurred vision occurred in 10 patients taking chloroquine (Aralen) phosphate, which is currently being used for a variety of diseases including malaria, lupus erythematosus, arthritis, and infestation with intestinal parasites. Chloroquine has a low incidence of toxicity. However, the corneal changes resulting in some patients taking the drug lead to symptoms (haloes around lights and blurred vision) suggestive of glaucoma. The change in the corneal epithelium varied from diffuse discrete white depositions to yellowish discrete dots grouped at the level of the epithelium and Bowman's membrane. The configuration of the depositions was diffuse in some cases, but most were linear. The maximal involvement was usually in the central portion of the cornea, with the area just below the pupil showing the greatest concentration.

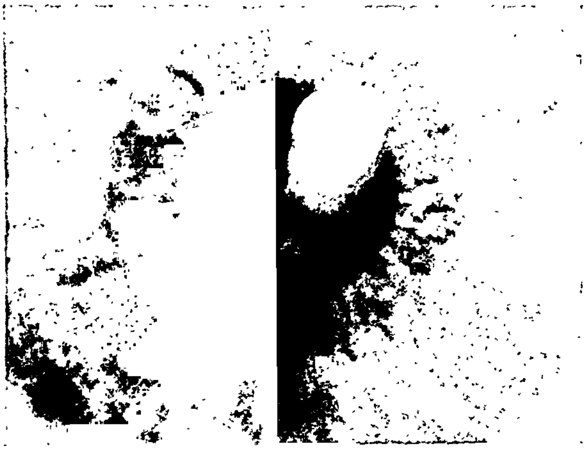
Some of the patients did not have any complaints about their vision. However, four sought ophthalmological help because they saw haloes around lights at night. All four had been told nothing was wrong and it had been intimated that they were suffering from "nerves." This diagnosis was made because the change is a slight one and careful examination with the biomicroscope (slit-lamp) is necessary to see the alteration in the cornea. When the disease is further advanced it is quite easy to see the pigment deposits. Reduction of visual acuity was not seen even though patients complained of blurring of their vision. When these patients were tested with Snellen charts their visual acuity was not lower than it had been prior to drug therapy. In some cases the granular appearing deposits became quite dense and assumed a more or less yellowish appearance. The density of the opacification of the cornea does not seem to be definitely related to the amount of drug taken. A patient taking 1,000 mg. of chloroquine daily for three years showed less change than one taking 250 mg. daily for nine months (see figure).

Twenty-two patients exhibiting the same corneal changes were described by Hobbs and Calnan.[1] In most of their cases, the corneal abnormalities regressed when the drug therapy was stopped. Our cases showed the same happy results occurring two to four months after therapy was stopped. However, Hobbs and Calnan reported one case in which visual acuity continued to decrease even after therapy was stopped.

Corneal changes of a different nature (edema of the corneal epithelium) have been reported in patients taking quinacrine (Atabrine) hydrochloride which is chemically related to chloroquine.[2] No edema was seen in our patients or was reported by Hobbs and Calnan.

Yellow staining of the conjunctiva and cornea occurred in workers in contact with quinacrine dust in a factory where the drug was manufactured. The staining was interpreted as actually representing the drug itself.[3] No conjunctival involvement was seen in our patients and the blue haloes seen by quinacrine workers are different from the blurred vision and haloes noted by patients taking chloroquine.

There is evidence chloroquine is widely stored in the structures of the body. In two of our most severely involved cases the patients appeared to have a faint fluorescence of the involved cornea when exposed to the Wood's light (ultraviolet). This possibly indicates that it is the drug itself which is deposited in the corneal epithelium because the drug does fluoresce. In less involved cases there is no fluorescence. It is too early to state whether or not chloroquine is stored in the lens epithelium, but this seems a definite possibility.



Linear and diffuse pigment deposits in central corneal epithelium of 48-year-old woman treated with chloroquine for arthritis (250 mg. daily for nine months).

Summary

Ten patients exhibiting discrete opacification of the corneal epithelium were taking chloroquine (Aralen) phosphate for arthritis or lupus erythematosus. The changes appear to be reversible on cessation of the drug therapy. Not all patients complained of visual problems but all showed corneal abnormalities with the biomicroscope. Some noted haloes around lights, a symptom which may lead to a mistaken diagnosis of glaucoma.

PURPURA DUE TO CHLOROTHIAZIDE (DIURIL)

Manuel O. Jaffe, M.D.
and
Robert R. Kierland, M.D., Rochester, Minn.

Chlorothiazide (Diuril) is an orally administered, nonmercurial, diuretic agent. Chemically, it is known as 6-chloro-7-sulfamyl-1,2,4-benzothiadiazine-1,1-dioxide.[1] It was made available commercially only this year; but, in its use thus far reported, the absence of toxic and otherwise undesirable side-effects has been especially noted.[2]

Ten of 51 patients observed by Hollander and Wilkins [2a] experienced slight to moderate weakness and fatigability, which usually disappeared with continuous treatment. In several, this weakness was associated with a feeling of mental depression, and, in a few of these, the level of serum potassium was reduced. Five patients complained of temporary mild nausea, especially when given 500 mg. of chlorothiazide in single doses. Other uncommon side-reactions included muscle cramps, flushing, lightheadedness, and paresthesias.

The potential development of clinical symptoms and signs of fluid and electrolyte imbalance resulting from chlorothiazide therapy has been stressed by all investigators.[2]

So far as we know, purpura resulting from the administration of chlorothiazide has not been reported in the literature. Two patients with such effects have been seen recently at the Mayo Clinic, and their cases are described here.

Report of Cases

Case 1.—A 66-year-old man was seen because of an eruption of two weeks' duration on his legs. The patient said he had taken chlorothiazide for one month several months before being seen at the clinic but had stopped for no definite reason. Two weeks before the present examination, he began again to take the drug, 500 mg. twice a day. Within two days after resuming chlorothiazide therapy, he noted the appearance of a petechial eruption about both ankles with subsequent involvement of the dorsa of the feet and hands and the distal half of both lower legs. The patient had continued to take chlorothiazide up to the time he was seen at the clinic. He denied bleeding from any of the body orifices or the gums. Four years previously he had given a history of easy bruising and prolonged bleeding, though examination at that time was nonrevealing. He denied the use of other drugs.

The patient was admitted to the hospital. The pertinent dermatological findings consisted of a confluent, symmetrical purpura involving the ankles and lower half of both legs. There were scattered petechiae involving the dorsa of the feet and hands. The patient also had keratoderma of the palms and soles and intertrigo of the inguinal areas. Hematological examination, including tests of the bleeding and clotting mechanisms, gave results within the limits of normal.

The patient was treated with bed rest and diphenhydramine (Benadryl) hydrochloride. The use of chlorothiazide was discontinued. During 10 days of hospitalization, 85% of the purpura cleared with no new lesions appearing during that time.

Case 2.—A 70-year-old man with congestive heart disease had been a patient at the clinic for many years. He had been receiving mercaptomerin (Thiomerin) sodium for three years and digitoxin preparations and ammonium chloride for two years. In January, 1958, he had been instructed to take chlorothiazide, 500 mg. twice daily three times a week.

In June, 1958, the patient showed dermatosis on his hands. Examination at this time revealed petechiae and purpura symmetrically distributed on the dorsa of the hands and about the ankles. Hematological examination, including tests related to the bleeding and clotting mechanisms, gave results within normal limits except for a count of only 94,000 platelets per cubic millimeter of blood. Continued use of digitoxin and ammonium chloride was advised, but chlorothiazide and mercaptomerin were no longer prescribed.

During the next week the amount of purpura and number of petechiae increased, with spread of the lesions to involve the lower half of the legs and the forearms. The patient's condition merited the use of mercaptomerin, and this was given without obvious increase in the severity of the purpura.

During the next two weeks, there was complete resolution of the petechiae and purpura. Throughout this time, digitoxin, ammonium chloride, and mercaptomerin were administered without apparent toxic effect. Their use has been continued to the time of writing without recurrence of purpura. Reappearance of purpura followed promptly, however, after chlorothiazide was given again in a single dose of 500 mg.

Summary

Previously reported undesirable side-effects of chlorothiazide (Diuril) therapy have been primarily those related to fluid and electrolyte imbalance.

From the Section of Dermatology, Mayo Clinic and Mayo Foundation. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

At this clinic, two cases of purpura resulted from the administration of this drug.

COUNCIL ON FOODS AND NUTRITION

METABOLIC AND BIOCHEMICAL CHANGES IN NORMAL PREGNANCY

Icie G. Macy, Ph.D., Sc.D., Detroit

The following is one of the six papers presented at the symposium on "Nutrition in Pregnancy" in Columbia, Mo., Oct. 11, 1957. This symposium was sponsored by the Council on Foods and Nutrition with the cooperation of the Boone County Medical Society, the University of Missouri School of Medicine, and the Adult Education and Extension Service of the University of Missouri.

Philip L. White, Sc.D., *Secretary.*

Many inherent metabolic and biochemical changes occur at the time of and after conception. Gestation presents three recognizable phases: (1) the preimplantation period that extends for approximately two weeks after conception; (2) the two-to-eight-week interval during which major organogenesis takes place; and (3) the period of most rapid prenatal and maternal growth, which extends from about eight weeks to term.

Metabolic and Functional Changes in Pregnancy

The implantation of the fertilized ovum causes the regulatory and functional mechanisms of the body to be thrown out of balance and results in a disturbed physiological state. The effects are observed in upsets in the gastrointestinal system—a decrease in appetite resulting in reduced food consumption, and nausea, sometimes with vomiting, which may result in a loss in weight. The results of metabolic changes may be seen in the level or distribution of blood components, in the level of urinary components, in the retention of nutrients, in the composition and function of the blood cells, in hormonal secretions, and in the composition and function of the placenta.

Alterations in Hormonal Secretions.—The three hormones primarily concerned in reproduction are the gonadotropins, the estrogens, and progesterone.[1]

Gonadotropins can be detected in the serum and in the urine a few days after the first missed menstrual period and continue to increase rapidly, reaching the maximum in about 50 to 70 days. They are believed to work in conjunction with the corpus luteum, causing it to persist and play a dominant role in organogenesis and growth of the fetus until about the fourth month of pregnancy. At the height of production, the gonadotropins may be excreted at a rate of 40,000 to 200,000 rat units per 24 hours. This level of excretion is maintained for a short time; by the 110th to the 120th day, it decreases to 5,000 to 10,000 rat units per 24 hours, a level maintained until the end of pregnancy. In cases of disturbed gestation, a late rise in both serum and urinary gonadotropins may occur. Biological tests of pregnancy depend on the presence of gonadotropins.

Progesterone, the corpus luteum hormone, is secreted until the third or fourth month of pregnancy. It stimulates the occurrence of secretory changes in the endometrium in preparation for the implantation of the fertilized ovum about the sixth day of the luteal phase of the ovum. By the third week of gestation, the placenta has grown and has developed to the point of initial functioning, producing some progesterone. Increased growth and function of the young metabolically active placenta permit it to take over the formation of progesterone between the second and third months of gestation, thus continuing the conditioning of the endome-

---

trium to provide for the nourishment of the conceptus. The reduction of progesterone is measured by its metabolites, pregnanediol and pregnanolone, and it is excreted as glycuronides of these substances. Maximum secretion is usually reached around the 220th to the 240th day. At term, values of the pregnanediol complex may fall between 50 and 100 mg. per 24 hours. After delivery, this hormone disappears rapidly from the urine.

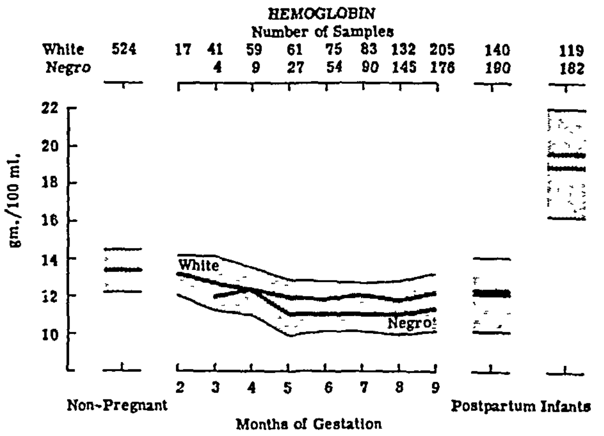

Fig. 1.—Trend of median hemoglobin levels of white, nonpregnant women, of selected white and Negro women during gestation and after delivery, and of their respective newborn, term infants. The 10th-90th percentile range for combined racial groups serves as standard for normality.

The pattern of estrogen level is similar to that of pregnanediol, low in early pregnancy with a slow increase through gestation. It does not increase appreciably until about the 100th day, with the greatest increase occurring in the last half of pregnancy, reaching values of 40,000 to 50,000 mcg. per 24 hours and attaining its maximum about 10 days before delivery. Estrogen and progesterone are maintained at high blood concentration levels during pregnancy; they stimulate growth and functional changes in the breasts and suppress the lactogenic function of the pituitary gland until delivery, when the pituitary gland stimulates the mammary glands to secrete milk.

The alteration in steroid metabolites during normal pregnancy has provided a valuable index of the adaptation of the adult organism to pregnancy.[1] The ketosteroid components in the urine of pregnant women differ quantitatively and qualitatively from those found in the urine of nonpregnant women. Of the 19 ketosteroids that have been characterized, 11 have been found in the urine of pregnant women. These observations furnish evidence that pregnancy induces alterations in the mechanisms of production or metabolism of the steroid precursors.

Placental Development.—During pregnancy, the growth rate of the placenta does not parallel that of the fetus, since the former attains its maximum size early in gestation. In the seventh month of pregnancy, the ratio of fetal weight to placenta weight is about 3.7:1; at term it has increased to 7.5:1. The wet weight of placentas ranges from 325 to 1,000 Gm., with an average of about 580 Gm. Large birth weights are not indicative of large placentas.

The placenta is essentially an organ with a nutritional function; it is well supplied with carbohydrate, protein, fat, enzymes, hormones, and minerals. Though there is a dearth of information about the progressive changes in the chemical composition of the placenta, under normal conditions its chemical composition during gestation varies to suit the demands made on it by the growing fetus. For example, the fat and carbohydrate contents are reduced in the last quarter of pregnancy; the vitamin content of the placenta increases during the course of pregnancy and then decreases near its termination.

Fetal nutrition depends, to a large extent, on the efficiency of the transmission of material across the placental barrier. The area of contact between maternal and fetal circulations has been estimated as between 10 and 13 sq. m. Only materials that can be carried in solution by the blood and can pass through the semipermeable wall of the chorionic villi can penetrate this barrier. Proteins of large molecular structure, with the exception of antibodies, are not transferred, whereas amino acids and proteoses are. Fetal fat is synthesized from lipid components passed from the mother's blood to that of the fetus. Chemically it is quite different from the body fat of the mother; fetal fat is richer in palmitic acid and contains less oleic and stearic acids. Vitamin D, ascorbic acid, thiamine, and

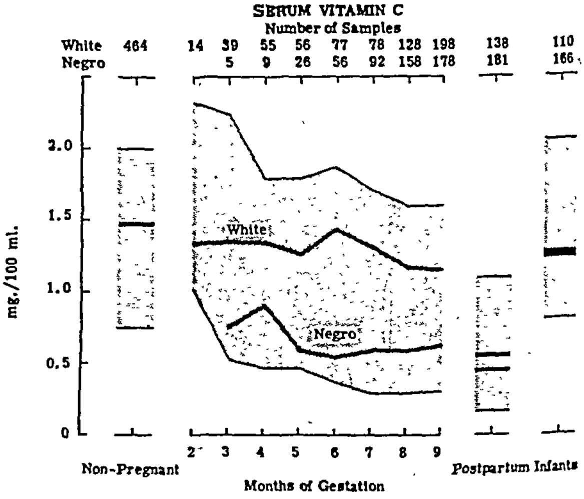

Fig. 2.—Trend of median serum vitamin C levels of white nonpregnant women, of selected white and Negro women during gestation and after delivery, and of their respective newborn, term infants. The 10th-90th percentile range for combined racial groups serves as standard for normality.

riboflavin are present in the human placenta [2] and are passed through it in regulated amounts. Vitamin A and carotene are passed through the placenta in less regulated amounts.

The placenta may well be considered an endocrine gland, since hormones similar to those of the pituitary gland have been demonstrated and since endocrine functions of the ovary are duplicated. Needham [3] pointed out the high content of ascorbic acid in the corpus luteum and the fact that it paralleled progesterone; he then assumed that ascorbic acid may be necessary to the production of the hormone. Values for ascorbic acid in the corpora lutea of nonpregnant women range from 24.8 to 48.3 mg. per 100 Gm.; for women in the second to fifth month of pregnancy, the values are 42.3 to 148.7 mg. per 100 Gm. The ascorbic acid content of the placenta is greater in the early months of pregnancy when its metabolic activity is greatest. The ascorbic acid content of an infant at birth averages 38 mg. per 100 Gm. of tissue; it decreases to 10.8 mg. per 100 Gm. during the first four months after birth. Excretion of ascorbic acid in the urine of the newborn infant [4] would indicate that there must be a plethora of this vitamin for fetal growth and development.

At the fourth month of development, the fats and lipids of the placenta are present in greater quantity in relation to the weight of the fetus than at any other time. In the developing placenta, there is disintegration of the lipids, releasing fatty acids, phosphorus, and choline. In comparison with values of other tissues, niacin is the only one of the B vitamins that is present in relatively large amounts.

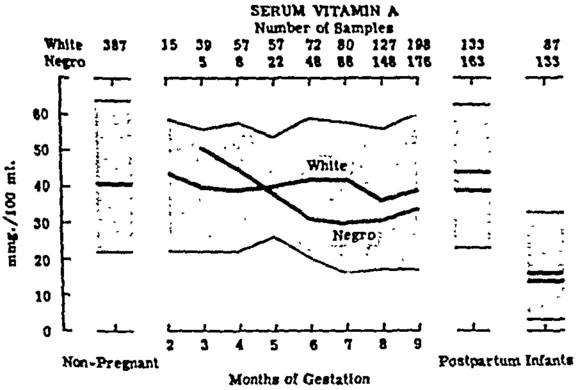

Fig. 3.—Trend of median serum vitamin A levels of white nonpregnant women, of selected white and Negro women during gestation and after delivery, and of their respective newborn, term infants. The 10th-90th percentile range for combined racial groups serves as standard for normality.

Basal Metabolism.—The basal metabolic rate falls from a normal to a subnormal level during the third to the fourth month of gestation. From this point, a steady increase is noted that amounts to 13% or more in excess of the rate conditioned by the gross increase in body weight. The basal metabolic rate does not differentiate between the tissues with high metabolic activity, such as the placenta, the fetus, and organs of both mother and fetus, that are more active than others. Basal metabolism is also influenced by increased thyroid function, as demonstrated by the steady increase of blood iodine from the second to the tenth month and by a decrease in blood iodine in the first two weeks of puerperium. Anatomic studies of thyroid glands obtained at autopsy from pregnant women [5] reveal larger follicles with abundant colloid and, at the same time, definite signs of cellular hypertrophy when compared with thyroids from nonpregnant women. Experimental studies suggest a greater need for thyroid hormone during pregnancy.

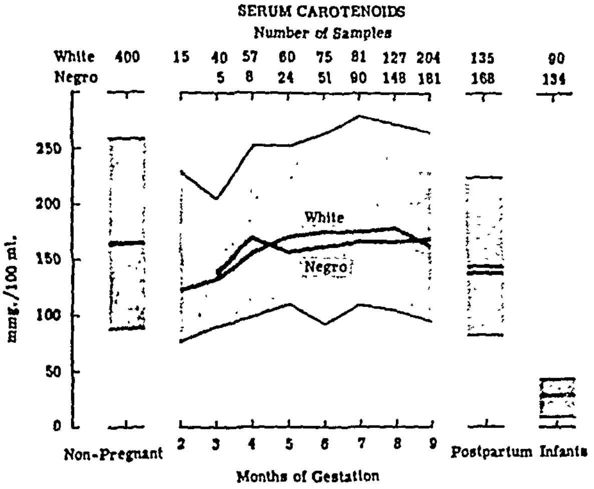

Fig. 4.—Trend of median serum carotenoid levels of white nonpregnant women, of selected white and Negro women during gestation and after delivery, and of their respective newborn, term infants. The 10th-90th percentile range for combined racial groups serves as standard for normality.

Other Hormonal Implications.—Loss of appetite, reduction in food intake, and disturbed gastrointestinal equilibrium in the preimplantation and organogenesis phases of pregnancy may well result from the excessive amounts of certain hormones elaborated by these glands [6] and from the morphologic and functional changes which they bring about in the digestive tract. The efficiency of absorption and of enzyme production is dependent on hormonal support. Recent studies show how the growth hormone produced during pregnancy increases nitrogen retention in the tissues in the form of protein.[7] It aids nitrogen conservation whenever dietary protein and carbohydrate are in short supply. This hormone or its companions influence fatty acid and ketone body metabolism.[8] Pregnancy increases vitamin B_{12} absorption.[9] Parathyroid hormones have been shown to act as biological regulators of calcium metabolism.

Blood Volume Increases.—There is an increase in plasma volume during pregnancy that averages approximately 25% at term over the nonpregnant value. A sharp increase occurs through the second trimester and during the first half of the third trimester, after which the plasma volume tends to remain constant or to decrease. In evaluating results of blood studies during pregnancy, a major physiological influence is known to be the change in blood volume.[10]

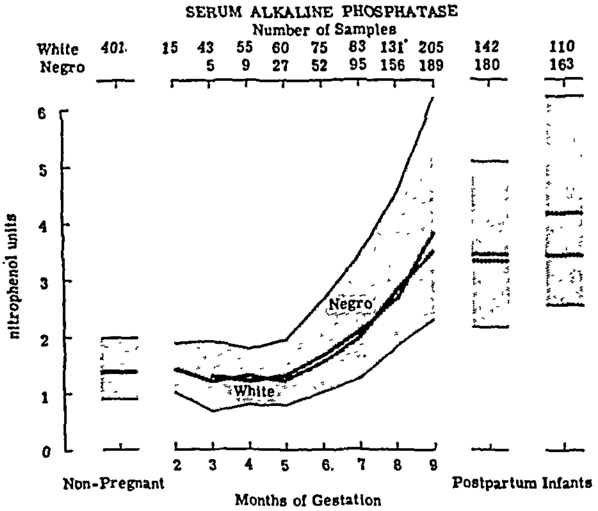

Fig. 5.—Trend of median serum alkaline phosphatase levels of white nonpregnant women, of selected white and Negro women during gestation and after delivery, and of their respective newborn, term infants. The 10th-90th percentile range for combined racial groups serves as standard for normality.

Biochemical Changes

During pregnancy many biological changes occur. The liver, kidneys, adrenals, and other vital organs develop functional activity commensurate with the stage and demand of gestation. Single determinations contribute little to the evaluation of biochemical individuality and customary responses; however, successive determinations performed as metabolic and physiological functional changes are taking place show individual patterns and deviation from established patterns.

Blood Determinations.—Any interpretation of physiological trends during gravidity, however, must recognize alterations in blood volume, since blood volume increases. If there are no changes in the concentration of the blood constituents with pregnancy, it is obvious that there are increased amounts in the bodies of mother and fetus. An increase in concentration indicates an even greater increase in the supply available.

Until methods for determining blood volume become easier to administer to groups of individuals, we have assumed that, if differences in gestational weight changes are not appreciable among healthy female subjects, the blood volume changes are similarly not significant. This assumption is necessary for comparisons of the concentrations of several blood components from the various groups at equivalent stages of gestation. In our studies, the characterization of the various groups suggests that, in the interpretation of the data on the basis of nutritional status, investigations of racial characteristics, of inequality of nutrient intake, and of prenatal care should also be undertaken.

We have presented observations[11] made on selected subjects who successfully completed gestation and delivery without any unusual disturbance or disease and who were delivered of healthy, full-term infants weighing at least 2,500 Gm. (5.5 lb.). Criteria for selection included consideration of medical history, clinical course during pregnancy, and outcome of gestation, with respect to both mother and child. Excluded from the group were women with physical structural defects, congenital or acquired, and those in whom malnutriture or disease had left recognizable clinical effects so serious that their health might have been permanently impaired. If either mother or infant were to be omitted for any of these reasons, both were excluded. Such conditions as syphilis and toxemia during current pregnancy were bases for categorical exclusion from the selected group. In some instances, obstetric judgment combined with pediatric consultations in relation to the condition of the infant were determining factors. Women whose deliveries involved operative procedures were excluded as well as those who were in labor over 24 hours. The blood values for 48 nonpregnant white women provided a basis for observing the physiological alteration from the nonpregnant to the pregnant state; those values for the selected group of 425 patients, chosen because they were free from clinical manifestation of disease, provided average and range values that may be used as standards for departures from health.

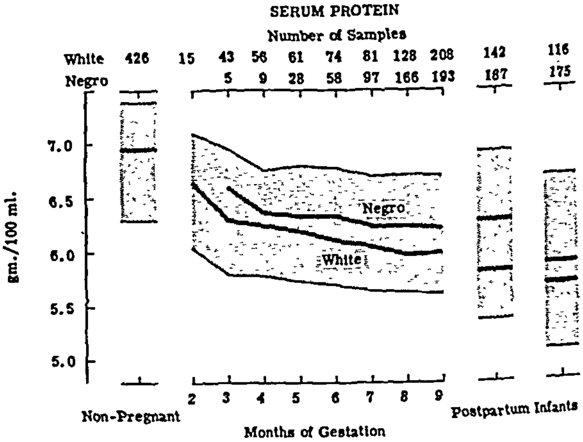

Fig. 6.—Trend of median serum protein levels of white nonpregnant women, of selected white and Negro women during gestation and after delivery, and of their respective newborn, term infants. The 10th-90th percentile range for combined racial groups serves as standard for normality.

In obtaining data for blood composition, unaccountably high or low results may occur which may not be true values. Such figures were eliminated by including values in the 10th to 90th percentiles, which characterize the usual physiological course during pregnancy. The medians and the 10th to 90th percentile ranges for hemoglobin, serums total protein, vitamin A, carotenoids, vitamin C, and alkaline phosphatase are presented. Data are also given for nonpregnant women, for the selected white and Negro women during pregnancy and for one to eight days post partum, and for their full-term infants one to nine days after birth.

Hemoglobin.—The medians and ranges for hemoglobin throughout pregnancy were lower than those of the nonpregnant women (fig. 1). The range of levels for white women was higher than the range for Negro women, indicating a difference in the racial groups. The median hemoglobin values for women of the white race were 0.7 to 1 Gm. higher than those for women of the Negro race during the last months of pregnancy. Selected white infants displayed hemoglobin levels higher by as much as 1 Gm., and the median levels were approximately 50% greater than the values of their respective mothers.

The extent to which hemoglobin will be formed depends, in large measure, on the availability in the body of iron and organic components for porphyrin formation and of essential amino acids for globulin formation. The number of organs and components in the body and the food components that converge to help perfect the synthesis, the metabolism, the distribution, and the destruction of hemoglobin are legion. The mechanisms that control the distribution of essential amino acids are little understood. Normally, the fetus acquires a reserve store of iron from the maternal organism via the placenta, especially during the last trimester of pregnancy. The placenta appears to conserve hemoglobin for fetal construction and reserves at the expense of the mother. An overstrain on the function of hematogenesis is shown by the mild secondary anemia, common in pregnancy. The physiological anemia (normocytic) of pregnancy is due to dilution by blood volume increase and causes no radical change in the alteration of the blood picture, since the reduction in hemoglobin, erythrocytes, and hematocrit is in direct proportion. To what extent particular hormonal factors in pregnancy alter the rate of the blood-building process and the development of an anemic state in pregnancy is being investigated.[12]

Serum Ascorbic Acid.—The serum of nonpregnant white women had higher concentrations of ascorbic acid than that of the selected white women in the first trimester of pregnancy (fig. 2). A downward trend throughout pregnancy extended into the postpartum period, but throughout gestation the levels of the white women were much higher than those of the Negro women. The ascorbic acid levels of the Negro women, though much lower earlier in pregnancy, did not show as much decline before delivery. The ascorbic acid concentrations in infant blood were almost alike for the two races, but the range was higher for white infants.

A shortage of ascorbic acid in the diet during pregnancy may thwart the growth impulses of the mother and her offspring in utero by impairing physiological function. Average serum concentrations of this vitamin for infants are two to four times that of the mothers' serum. This fact gives credence to the theory that the placenta exerts selective control over the passage of ascorbic acid and may act as a barrier to re-entrance of the vitamin into the maternal circulation.

Without doubt, endocrine changes exert some influence on maternal blood levels of ascorbic acid, just as the ascorbic acid content of the adrenal gland is high in pregnancy. Ascorbic acid and proteins are involved in the metabolic mechanism of the adaptation syndrome occurring during the stress of physiological disturbances in pregnancy. It is generally recognized that fetal needs take priority over maternal needs for this vitamin and that the fetus may build up a substantial reserve of it at the expense of the mother.

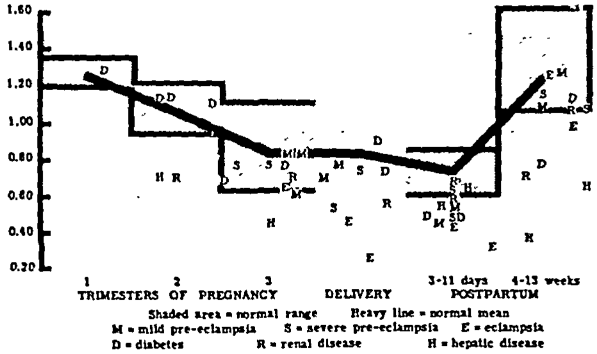

Fig. 7.—Albumin:globulin ratio in maternal blood during and after pregnancy.

Serum Vitamin A.—The median concentrations of serum vitamin A of nonpregnant white women and selected white patients in the first trimester were not different (fig. 3). The median values were consistently higher for white than for Negro women during the last five months of gestation and post partum. Although the difference between the medians for white and Negro infants was small, that of the Negro was lower. Vitamin A and its precursors, the carotenoids, have special roles in the formation of the epithelial cells during organogenesis, in the maintenance of their integrity, and in the formation of bone.[13]

Serum Carotenoids.—The median serum carotenoid level for nonpregnant white women was higher than that for the selected white subjects in the first trimester (fig. 4). For both white and Negro subjects, however, upward trends in early pregnancy were followed by leveling off after the sixth month and lowered values post partum. The levels for white and Negro infants were not different but were much lower than those of their mothers.

Serum Alkaline Phosphatase.—The pattern for serum alkaline phosphatase is different from those for hemoglobin and the vitamins, because its concentration in serum more directly parallels skeletal growth and maturation in the fetus and mineral storage in the maternal organism. The trend was definitely upward through the ninth month, with the levels decreasing in the puerperium (fig. 5).

Alkaline phosphatase enzymes are widely distributed in the organs and tissues of the body, occurring in high concentration in bone and ossifying cartilage. Their activity is related to calcium homeostasis [14] and vitamin D nutriture. Data demonstrate that physiological changes in alkaline phosphatase concentration occur with regularity during the reproductive cycle, the magnitude of change corresponding in large measure to anatomic growth and development.

* Values in Gm./100 cc. of plasma.

† According to estimated date of confinement, determinations in first trimester were made in 4th to 9th week of pregnancy; those in second trimester were made between 15 and 25 weeks of gestation; those in third trimester were made after 28 to 41 weeks of pregnancy.

‡ Fourteen subjects. In all other groups, number of determinations also is number of subjects.

Blood Proteins.—Levels of total serum protein of nonpregnant white women were higher than medians for white and Negro women at any time during gestation (fig. 6). For women of both races, the trend of serum protein concentrations was downward throughout pregnancy, the median differences ranging from 0.11 to 0.46 Gm. per 100 ml. of serum. The protein levels of infants were lower than those of their respective mothers, and both the median and the range for the Negroes exceeded those of the white race.

The intensity with which the maternal body builds active body tissue, the rapidity with which labile protein and mineral reserves are accumulated, and the extent of alterations taking place in hormonal excretions may influence the level of serum protein. Physiologically, total serum protein has less significance than the quantities and properties of the several component proteins, each one differing in composition and performing widely different physiological functions in the body.

Observations of levels of total serum protein, albumin, and alpha$_1$, alpha$_2$, beta, phi, and gamma globulins during pregnancy and subsequent to delivery demonstrated a characteristic pattern of distribution of these components for uncomplicated pregnancy; the pattern is disturbed in complicated pregnancy,[15] however, and some diseases present distinctive patterns (fig. 7).

Electrophoretic analysis of the proteins in plasma or serum provides a more detailed and reliable picture of this labile biological system than do other methods, although values are frequently lower than those obtained by chemical methods. Data for women during and after both uncomplicated and complicated pregnancies demonstrated the variations attributable to individual physiological differences among women, as well as differences in the time of the cycle during which the blood samples were drawn. In general, trends for albumin and gamma globulin were downward; trends for alpha$_1$, alpha$_2$, beta, and phi (fibrinogen) globulins were upward until delivery or at term; subsequently, the trends were reversed and the values approached those of the nonpregnant state. The plasma albumin: globulin ratios for each period in the reproductive cycle showed the decreases consequent to lowered albumin concentration and higher globulin concentration during pregnancy, with the return post partum toward the nonpregnant relationship. During the first trimester (preimplantation and organogenesis phases), the decreases in albumin gamma globulin were obvious; in the second and third trimesters (growth phase), the concentrations of albumin and gamma globulin in total protein were reduced significantly.

Summary

Pregnancy causes the regulatory and functional mechanisms of the body to be thrown out of balance. The effects of these imbalances are frequently seen as upsets in the gastrointestinal system. Results of the metabolic changes are observed in the composition of the blood cells and in the differing levels and distribution of the blood components. The levels of urinary components, the changes in hormonal secretions, the greater retention of nutrients, and the composition and function of the placenta are all indications of the metabolic changes that take place at the time of or after conception.

NEW ANATOMICAL NOMENCLATURE.—An International Anatomical Nomenclature Committee was set up, and the work of this Committee resulted in the Paris Nomina Anatomica of 1955. . . . Major changes are few. One or two structures familiar in clinical practice, are however, affected. The circumflex nerve, for example, is now the axillary nerve, even though it quickly leaves the axilla and though its accompanying artery is still called the posterior humeral circumflex artery. The internal mammary artery becomes the internal thoracic artery. The accessory nerve, which has always been a little troublesome, is now described as having an internal branch (cranial part), and an external branch (spinal part). The moderator band of the right ventricle is to be known officially as the trabecula septomarginalis, and certain details of the heart valves are changed. . . . At present, in British textbooks, it is usual to name the cusps of the pulmonary valve posterior, right, and left; in the new list they are given as anterior, right, and left. Similarly the cusps of the aortic valve have been changed from anterior, right, and left to posterior, right and left. . . . A name has now been found for the "Artery Without a Name." One has often wondered why a vessel which supplies one-eighth, let us say, of the body with blood should have been called the innominate artery, or, what sounds even more casual to English ears, the B. A. (1895) term—Arteria Anonyma. Now it is to be called the brachio-cephalic trunk—not an elegant name perhaps, but at any rate, "nomen proprium," a name of its own.—R. M. Livingstone, The New Anatomical Nomenclature, *Annals of the Royal College of Surgeons of England*, May, 1958.

HISTOPLASMOSIS

HISTOPLASMOSIS was first described in 1906 and until about 1940 it was considered to be an acute, progressive, almost invariably fatal disease. It is now recognized that in addition to the progressive disseminated type there is a much commoner type that is benign, self-limited, and often asymptomatic.[1] According to Tegeris and Smith[2] the case fatality rate in epidemics is about 1.2%. The distribution seems to be world-wide but the disease is more prevalent in rural than in urban areas and in some rural regions than in others.[3] The causative fungus, Histoplasma capsulatum, is found in the feces of birds (especially domestic fowl), bats, dogs, and various other mammals, hence it is commonly found in the soil.

Primary infection with the development of a single tuberculoid nodule in the lung is almost always of the benign type but, if there is an overwhelming exposure to contaminated dust, multiple pulmonary lesions may result from hematogenous spread. In older patients about 50% develop cutaneous or mucocutaneous lesions (nodules, papules, ulcers, abscesses, and furuncles). The spleen may be enlarged. The patient may have a cough which is usually unproductive, chest pains of varying intensity, loss of weight, increased fatigability, and general malaise. The condition usually is first suggested when the characteristic changes are seen in a roentgenogram of the chest. As in the case of tuberculosis, a positive skin test indicates previous contact with the causative organism but gives no information regarding activity. The complement-fixation test is the only serologic test that is of much value as an index of activity, but it is so complex that it is done only in a few special laboratories.[1]

The diagnosis is difficult because neither the clinical nor the x-ray findings are pathognomonic and the disease simulates many other conditions. In endemic areas histoplasmosis in white children up to age 18 is at least eight times as common as tuberculosis.[4] Many patients with pulmonary cavities due to histoplasmosis are still admitted to tuberculosis hospitals despite the absence of any positive evidence of tuberculosis. This is unfortunate because streptomycin (and also penicillin) is contraindicated in the treatment of histoplasmosis as it favors the growth of the organisms.

The benign type of this disease requires no treatment. In the effort to find an effective treatment for the progressive type many drugs have been tried and sometimes the results reported by one observer differ radically from those reported by another. Christie[3] used sulfonamides with good results even in patients with progressive lesions. For this reason he believes these drugs may be lifesaving. The response of the patients was not apparent for a week or two but within three or four weeks the patients were well and no relapses were observed. The most controversial drug is amphotericin B. Lehan and co-workers[5] found it relatively nontoxic and suggested that it might have some therapeutic usefulness. Later they reported improvement in patients with the progressive type of lesion when the drug was given by mouth but relapse when it was discontinued. Two patients given the drug intravenously showed marked clinical and bacteriological improvement but two others with far-advanced lesions treated in this way died. Christie stated that although some favorable results with this drug have been reported it is likely to produce chills and fever and may cause renal damage. Packard and co-workers[6] used cortisone and believed that the drug probably shortened the course of the disease and saved life but reserved its use until after two weeks of illness had elapsed. This allowed the body to develop an immune reaction. Immediate use of this drug might further the spread of the disease and suppress antibody formation.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

Additional positive steps were taken by the House of Delegates at the recent A. M. A. Clinical Meeting in Minneapolis for meeting the medical care needs of the indigent. It is my personal wish that all physicians will participate with their state and county medical societies in developing the best possible programs for public assistance recipients.

Currently there are a multiplicity of programs for medical care of the indigent under the Social Security Act. According to the law, each state must keep its programs for (1) old-age assistance, (2) aid to dependent children, (3) aid to the permanently and totally disabled, and (4) aid to the blind administratively and financially distinct. This separation leads to confusion, waste, and duplication.

To help correct this situation the Council on Medical Service recommended and the House of Delegates approved a resolution that the Social Security Act be amended by Congress to permit states to combine the present four public assistance medical programs into a single medical program, administered by a single agency and making available uniformity of services to all eligible public assistance recipients in the state.

Regarding the program administration by a single agency, the House concurred in the recommendation that each state medical association give serious consideration to the use of a "voluntary agency such as Blue Shield" or a "specific agency established by the medical society" for administering any funds provided under the public assistance provisions of the Social Security Act for medical care of the indigent.

Some state associations already use such administrative agencies, and I urge others to experiment with the use of similar mechanisms.

Because the medical profession has accepted the principle that the provision of personal health services to the needy is primarily the responsibility of the state and local governments, it now is our duty to see that the best possible programs are developed and administered at these governmental levels.

In communities where physicians prefer to provide care through their own charity, rather than being paid from welfare funds, I sincerely hope that definite programs will be established to assure that every needy person has the necessary physician's services to the extent available in the community.

Furthermore, I agree with the Council on Medical Service and the House that "medical societies establish formal liaison with governmental agencies concerned in the provision of health services to the indigent in their areas, and through such liaison they act in an advisory capacity to assure the adequacy of the health care of those who cannot meet the cost of such care through their own resources."

Finally, I believe that in some areas nonindigent and nondeserving persons now have access to public assistance services. Therefore, I concur with the Council and the House that indigent care committees must inform themselves regarding laws and regulations governing determination of eligibility and must examine both the validity of these standards and their application.

By its actions on the Council's recommendations the House has laid the foundation for a strong, medically sponsored program to implement existing policy statements concerning personal health services to the needy. It also has outlined a positive program of local action which will serve as a bulwark against further federal entry into the field of medical care. Let us provide the active and organized support needed to make the program a reality in every state and community.

Gunnar Gundersen, M.D.
La Crosse, Wis.

SCENES FROM THE MINNEAPOLIS MEETING

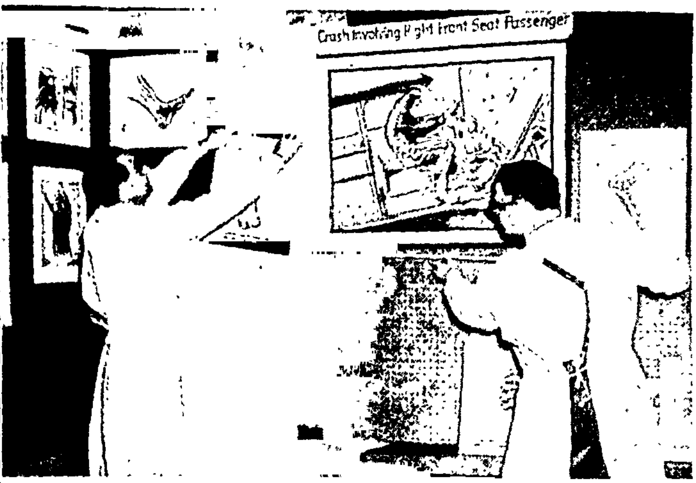
Left, A. M. A. House of Delegates during 12th Clinical Meeting in Minneapolis, Dec. 2-5, 1958.

Above, Reference Committee on Insurance and Medical Service meets to discuss resolutions introduced to House of Delegates.

Left, Dr. Gunnar Gundersen, La Crosse, Wis., A. M. A. President, addresses House of Delegates.

One of the many preconvention meetings was the Conference on Federal Medical Services.

General Practitioner of the Year, Dr. Lonnie Coffin of Farmington, Iowa, is welcomed to House of Delegates by Dr. E. Vincent Askey, House Speaker, and Dr. Louis M. Orr, A. M. A. President-elect.



Crash Involving Right Front Seat Passenger

Above, Dr. Charles V. Heck *(left),* University of Illinois College of Medicine, and Dr. Harry B. Hall, University of Minnesota Medical School, present Auditorium exhibit featuring fractures encountered by front seat passenger in auto crash.

Left, Dr. J. T. Lowe, Indianapolis, receives a copy of A. M. A.'s new pamphlet, "The Healthy Way to Weigh Less," being distributed at Council on Foods and Nutrition exhibit on weight reduction. Pamphlet will be mailed to all medical societies later this month.

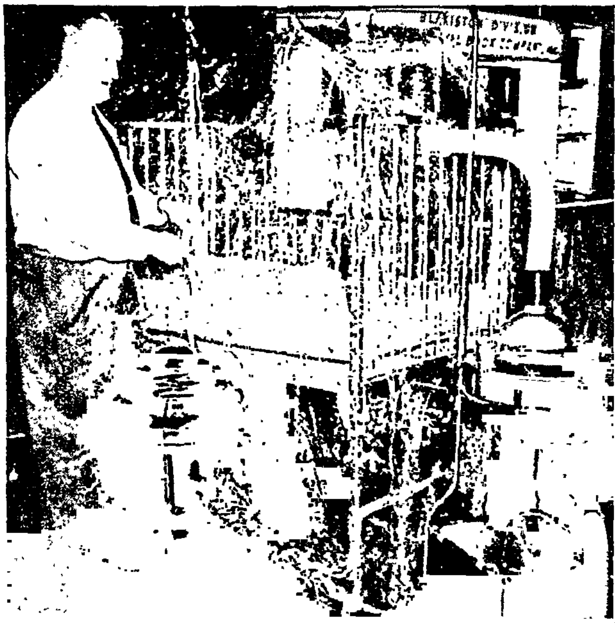
Right, Dr. Peter A. Salmon demonstrates his work with massive hemorrhage by local gastric hypothermia with wax models and a hypothermia machine. Dr. Edward W. Kieffer *(left),* Elmore, Ohio, was one of many physicians to study his work.

BLOOD SUPPLY.
CIRCULATION IS MAINTAINED FOR 30 MINUTES UNTIL THE CHEMOTHERAPEUTIC AGENT IS INTO THE TISSUE.

Chemotherapeutic application of isolated organ perfusion is outlined to Dr. Howard M. Frykman *(left)* of Minneapolis by exhibitors Dr. R. K. Ausman and medical technologist Sharon Semmill of the University of Minnesota.

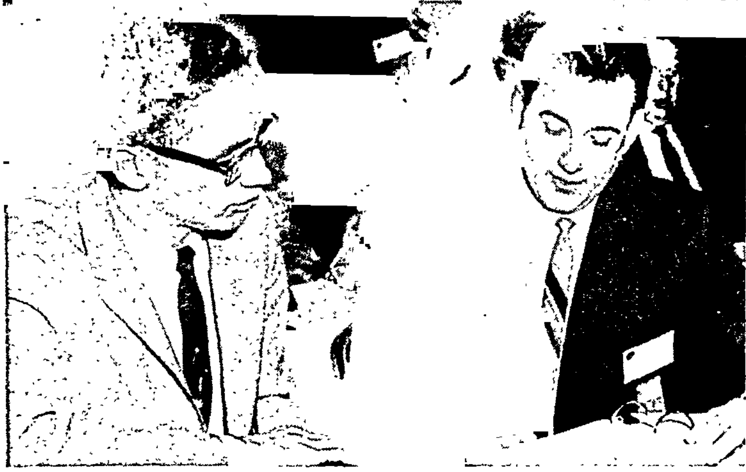
Twin coil artificial kidney is explained by Dr. John F. Maher, Georgetown University School of Medicine, to Dr. Joseph Rosenfeld *(right)* of Philadelphia.

Right, Tom Gardiner, rounding out 50 years of service on A. M. A. staff, attends his last Clinical Meeting before retiring Jan. 1. He checks operational schedule of meeting with his secretary for 16 years, Miss Rita Huster, in the Auditorium.



Above, Tom Creagh of Chicago was an early bird in setting up demonstration of cold steam humidifier in Industrial Exhibition.

Right, Dr. Herman Kleinman, in "Indian Medicine in Minnesota" exhibit in Auditorium, is awarded feathered finery for his work on Redlake Indian Reservation.



Seated as representatives of Student American Medical Association are Marvin J. Chapman *(left),* University of Wisconsin Medical School, and William Kirkham, University of Oklahoma Medical School. They are S. A. M. A. regional vice-president and treasurer respectively.

Mrs. Arthur E. Underwood of Vancouver, Wash., President of Woman's Auxiliary to A. M. A., addresses House of Delegates.

MEDICAL NEWS

ARKANSAS

County Society Aid for Research Laboratory.—The Pulaski County Medical Society gave $10,187 to the University of Arkansas Medical Center, Little Rock, Oct. 17 to establish a Virus Research Laboratory in the proposed new 2-million-dollar Research Wing to be built at the center. The check was presented to Dr. F. Douglas Lawrason, provost for medical affairs, by Dr. Hoyt Choate, society president, and Dr. Jerome S. Levy, chairman of the society's Committee for Distribution of Surplus Funds. The money will be matched by federal funds in the construction of the Research Wing. The government has allocated $1,066,000 to the university. Dr. Choate said the reserve money had been building up in the society's funds for a number of years. Out of a large number of possible uses that were considered, it was decided unanimously by the committee that it could best be utilized at the Medical Center.

CALIFORNIA

New Deadline for Heart Research Funds.—A new deadline—Feb. 1, 1959—has been established for applications for research funds from the Los Angeles County Heart Association. The deadline formerly was April 15. Decision to advance the final date for applications was announced by Dr. Mitchel D. Covel, chairman of the Research Committee. Dr. Covel said the earlier deadline is to the advantage of local investigators because their applications can be distributed by the California Heart Association through the state and in turn attract additional funds to local investigators from other chapters. As changes have been made in application methods, investigators are advised to contact the Heart Association at 660 S. Western Ave., Los Angeles, DUnkirk 5-4231, for a copy of the New Application Information bulletin. Under the new schedule, applications will be referred to study sections of the committee by Feb. 10. Final notification of awards will be made on June 1 and projects will be funded on July 1.

DISTRICT OF COLUMBIA

Campaign for Hospital Research Center.—Children's Hospital of the District of Columbia has launched a campaign to raise $460,000 to complete its new Research Center and finance other improvements to the hospital at a total cost of $1,117,357. Grants totaling $457,357 and a $200,000 pledge from the Variety Club of Washington, D. C., were received before the campaign opened. The Research Center is now under construction at Twelfth and W. Sts., N.W. Scheduled for completion in January, 1959, the building will cost about $800,000. The three-story structure will provide facilities for research in allergy, antibiotics, adolescent medicine, cystic fibrosis, hematology, psychiatry, renal diseases, and viral diseases. Movable partitions will allow rearrangement of research areas without extensive repairs. Research is currently conducted in scattered laboratories within the hospital. New parking facilities, air conditioning, an expended medical library, a psychiatric center, and a recovery room are among the other projects to be financed by campaign funds.

FLORIDA

Study of Caribbean Tropical Disease.—Twelve University of Miami graduate students in medicine and zoology will study tropical diseases and parasitology in Central America and the Caribbean as a result of a $19,000 educational grant received by the university from the National Institutes of Health, Washington, D. C. J. Walter Beck, Ph.D., associate professor of microbiology, will accompany six medical students to Costa Rica for a month's study of parasites and tropical disease. W. Henry Leigh, Ph.D., professor of zoology, and Dr. Ralph Jones Jr., chairman of the department of medicine, will supervise the training program. Another group of six graduate physicians who are residents specializing in internal medicine will undertake similar studies in Jamaica. In Costa Rica, the San Juan de Dios Hospital of San Jose will be headquarters while in Jamaica the training program will stem from the British Medical College of the West Indies.

HAWAII

Colonel Hughes Receives Award.—The Wellcome Prize was awarded to Lieut. Col. Carl W. Hughes, M. C., U. S. Army, Nov. 19, at the 65th annual convention of the Association of Military Surgeons of the United States. Colonel Hughes, a native of Missouri, is chief of general surgery service at Tripler Army Hospital in Honolulu. The Wellcome Prize is presented annually at the discretion of the association for "the best essay on medico-military affairs prepared by one of its members." The prize consists of a silver medal, a scroll, and an honorarium of $500. The Wellcome Prize essay for 1958 is entitled "Vascular Surgery in the Armed Forces."

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

MASSACHUSETTS

Workshop on Instrumentation.—A five-day Instrumentation Workshop will be held April 13-17, 1959, at Harvard Medical School, Boston, under the auspices of the Clinical Pathology Committee of the New England Society of Pathologists. The workshop covers actual participation in:

1. Use of Beckman DU spectrophotometer and
2. pH meters
3. Assembling ammeter-voltmeter for your own use
4. Trouble shooting on photometers
5. Studying blood pH methodology
6. Constructing spectral absorption curves in visible and ultraviolet
7. Photofluorimetry
8. Practical program of laboratory maintenance.

Registration should be made immediately.

MICHIGAN

Distinguished Citizen's Award.—The Dearborn Chamber of Commerce has announced that Dr. Sidney E. Chapin won its "Distinguished Citizen's Award" for 1958. The presentation was made Oct. 28. Dr. Chapin is secretary of the Michigan Heart Association, is chairman of both the Health Federation, United Community Services of Detroit, and Public Relations Committee of the Wayne County Medical Society, has served as chairman of Dearborn Public Health Committee and the Steering Committee of Child Guidance Project West Wayne County, and is the vice-president of Detroit Men's Council Navy League of the U. S.

MISSOURI

Name Chairman of Nutrition Committee.—Dr. Robert L. Jackson, chairman, department of pediatrics, University of Missouri School of Medicine, Columbia, has been appointed chairman of the Committee on Infant Nutrition by the Food and Nutrition Board of the National Research Council, Washington, D. C. The Committee on Infant Nutrition has the responsibility of accumulating and interpreting scientific data on infant nutrition, defining the unsolved problems, and pointing out areas for future research. It also advises the National Research Council on revision of recommended dietary allowances. Establishment of the committee was authorized by the Food and Nutrition Board last spring. Other members of the committee are Dr. Harry H. Gordon, Baltimore; Dr. Paul Gyorgy, Philadelphia; Wendell H. Griffith, Ph.D., Los Angeles; Dr. Charles U. Lowe, Buffalo, N. Y.; and Dr. Joseph A. Johnston, Detroit.

NEBRASKA

Psychiatric Institute Wins Award.—The Nebraska Psychiatric Institute received the 1959 Mental Hospitals Achievement Award of the American Psychiatric Association. The association's silver plaque was conferred on the Omaha institution "in recognition of its leadership in creating a statewide mental health program." The award was presented at the 10th Mental Hospital Institute by Dr. Mathew Ross, medical director of the American Psychiatric Association, to Dr. Cecil Wittson, director of the institute. The citation read: "Nebraska's decision to invest in a psychiatric research and training facility, rather than just adding more hospital beds, has paid dividends in a dynamic program that has benefited the entire state and aids the Dakotas and Iowa." Community clinics and orientation courses for clergymen, teachers, and general practitioners aided in the program. Nebraska has pioneered in the use of an interstate telecommunication system and closed-circuit television for training in psychiatric centers.

NEW YORK

Dr. Wagner Named Executive Director.—Dr. Herbert T. Wagner, Bronxville, became the new executive director of the Medical Society of the State of New York Dec. 1, it was announced by Dr. Leo E. Gibson, Syracuse, president of the society whose headquarters are at 750 Third Ave., New York City. Dr. Wagner will take over the management of the society's staff of 70 employees who work in the membership and directory departments, the Bureau of Industrial Health and Workmen's Compensation, the Bureau of Medical Care Insurance, and the Bureau of Public and Professional Relations. The society, which last year celebrated its 150th anniversary, also publishes the *New York State Journal of Medicine*. Dr. Walter P. Anderton, secretary of the society for many years, who formerly had the dual position of secretary-general manager, will continue as the society's elected secretary.

Establish Institute for Rheumatic Fever.—New York University and Irvington House have agreed to establish the Irvington House Institute for Rheumatic Fever and Allied Diseases as a part of New York University–Bellevue Medical Center. The institute will be housed in the new University Hospital. Irvington House will underwrite the cost of $500,000 toward the construction of the treatment, research, and clinical facilities. Both Irvington House and the Medical Center have been responsible for original research on rheumatic fever. Irvington House, at Irvington-on-Hudson, is a hospital and research center for children afflicted with diseases of the heart. Since its beginning in 1920, it has cared for over 5,800 children. The university and Irvington House, while joining in the creation and operation of the institute, will continue to function as autonomous, financially independent institutions. New York University–Bellevue Medical Center will appoint the central committee of the institute, to function as a communications center for the research programs in rheumatic fever and those allied diseases which are initiated by streptococcal infection. Members of the Irvington House Medical Advisory Committee will be nominated by the university and elected by the Irvington House board.

New York City

Hospital News.—A $350,000 project involving the installation of a postoperative recovery unit and expansion of the operating theatre and the x-ray department has been completed by The Bronx Hospital, Dr. Aaron A. Karan, hospital director, has announced. The three facilities are housed on the eighth floor of the main building. A $172,000 grant from the Ford Foundation paid for half the cost of the project. The other 50% expense was met by the Federation of Jewish Philanthropies and the hospital's own building fund resources.

NORTH CAROLINA

Dr. Warren Goes to Texas.—Dr. James V. Warren, professor of medicine at the Duke University Medical Center, Durham, has left to become chairman, department of internal medicine, University of Texas Medical School, Galveston. A Duke faculty member since 1952, Dr. Warren is known for his research on heart disease. Two years ago he visited Africa as a member of an international team which made a blood pressure study of giraffes, a project conducted under a contract between Duke and the U. S. Office of Naval Research to provide data related to the problem of blackouts among high-speed aircraft pilots. Dr. Warren served in 1952 as president of the American Federation for Clinical Research. He is a member of the editorial boards of the *"American Heart Journal," "Heart Bulletin,"* and the cardiovascular section of *"Excerpta Medica."*

PENNSYLVANIA

Philadelphia

Dedicate Quarters for New School.—The School of Allied Medical Professions of the University of Pennsylvania dedicated its new quarters at 39th and Pine Streets, Philadelphia, Nov. 25. The building is a completely renovated former convent. Following a tour by 90 guests representing local, state, and national health, rehabilitation, and educational agencies, Basil O'Connor, president of the National Foundation, spoke on "Careers that Count." The building makes it possible for various programs of the School of Allied Medical Professions to be housed under one roof. These programs include physical therapy, occupational therapy, medical technology, and oral hygiene. Administrative and instructional activities of the school were moved into the new quarters Sept. 1.

Dr. Hodes Named to Head Radiology Department.—The Board of Trustees of Jefferson Medical College has appointed Dr. Philip J. Hodes as professor and head of the department of radiology and as attending radiologist of Jefferson Hospital succeeding Dr. Russell L. Nichols. Dr. Hodes has been professor of radiology at the Medical School and at the Graduate School of Medicine, University of Pennsylvania since 1952. He has also been associate in radiology at the hospital of the University of Pennsylvania since 1955. In Philadelphia he is consultant for the U. S. Naval Hospital, The Veterans Administration Hospital, and Jeanne's Hospital; and in Washington, Walter Reed Army Hospital, and the Armed Forces Institute of Pathology. He is a diplomate of the American Board of Radiology and a past-president of the Philadelphia Roentgen Ray Society.

Begin Construction on Research Building.—The University of Pennsylvania School of Medicine has begun construction on its new Research Building, a $3,100,000 structure, to be devoted solely to medical science research. An additional building is planned for the department of biology and is to be located adjacent to the Medical Research Building. Classrooms, libraries, and offices of the School of Medicine Building, laboratories of the Medical Research Building, and the college's departments of biology and zoology will all be interconnected. The research building itself will be characterized by four seven-story towers connected by a common, central section. When completed the building will be occupied by the departments of microbiology and physiology, the Phipps Institute section of the department of public health and preventive medicine, the Harrison department of surgical research, and the Johnson Foundation for biophysical research. It is being financed by the university and the U. S. Public Health Service under the Federal Research Facilities Act. The University's contribution of $1,600,000 will be matched by a Public Health Service grant of $1,500,000.

GENERAL

Survey of Research in Tropical Medicine.—A survey to determine the adequacy of research and training in tropical medicine in the United States will be undertaken by the National Research Council, Washington, D. C., with financial support from the National Institutes of Health, the Department of Defense, and The Rockefeller Foundation. The foundation is contributing $26,000 over a three-year period. The survey will seek information on the status of tropical diseases which affect human beings and animals and are of economic importance, and will evaluate the research and development work now in progress. A special staff appointed by the National Research Council will conduct the study and formulate recommendations.

Award for Cancer Research.—The Ann Langer Cancer Research Foundation has announced an annual award of $500 for meritorious investigation in the field of cancer research, either clinical or laboratory. The award is being supported by the family of the late Bertha Goldblatt Teplitz. Competition shall be limited to physicians and other scientists under the age of 45. The Award Committee consists of Drs. Austin M. Brues, Israel Davidsohn, Danely P. Slaughter, Albert Tannenbaum, and William B. Wartman, of Chicago. Nominations should be submitted to Tiplitz Award Committee, 612 N. Michigan Ave., Chicago 11 by Feb. 1, 1959, and should be accompanied by a short one-page statement and biography.

Plans for New Library of Medicine.—Preliminary plans for the new building of the National Library of Medicine have been submitted to the Public Buildings Service, the Public Health Service has announced. The new building will be constructed on the grounds of the National Institutes of Health in Bethesda, Md. Plans call for 232,000 square feet of space, on five levels, three of which will be below ground level. The 85th Congress appropriated 7 million dollars for construction, which will begin in spring, and the building is expected to be completed in 1961, the 125th anniversary of the library's founding. The National Library of Medicine, operated by the Public Health Service of the Department of Health, Education, and Welfare, is reportedly the largest medical library in the world.

Prize for Medico-Surgical Film.—The "Annual Prize for Medico-Surgical Cinema," which comprises 100,000 francs cash (with possibility of being divided) and various other awards, will be given during the last session of the course of "Actualities Medico-Chirurgicales" at the "Nouvelle Faculte de Medicine de Paris" March 17, 1959. The didactic value of the film as well as its properly cinegraphic quality will be considered. Only the 16 mm. size film will be admitted. Candidatures and films are to be sent to the "Secretariat du Journal La Presse Medicale," 120 Boulevard Saint Germain, Paris VI°, prior to Feb. 15, 1959. Awards will be remitted to the authors of the best films. Contrary to the preceding years, all the films may be given awards, including those subsidized or produced by a laboratory or firm.

Chilean Physician Visits U. S. Schools.—Dr. Ramon Ortuzar, of Santiago, Chile, chairman, medical department, Catholic University of Chile, recently visited Georgetown University, Washington, D. C., to study ways and means of expanding and improving his institution's staff. He is visiting under a W. K. Kellogg Foundation grant to see how clinical medicine is taught in selected medical centers, and to study the relation between clinical medicine and basic science. At present, Dr. Ortuzar pointed out, the Catholic University of Chile admits only 35 students per class. Dr. Ortuzar has visited medical schools at the University of Colorado, Vanderbilt University, the University of Kansas, Western Reserve University, and Washington University of St. Louis. After leaving Georgetown, his schedule took him to Harvard, Johns Hopkins, Yale, Cornell, and Columbia.

Orthopedic Surgeons Meet in Chicago.—The 26th annual meeting of the American Academy of Orthopaedic Surgeons, will be held Jan. 24-29 at the Palmer House, Chicago. The presidential address will be given by Dr. H. Reton McCarroll the morning of Jan. 26. Papers to be presented by special invitation are as follows:

Experiments in Immunity in Cancer, Dr. Gordon Murray, Detroit.
Recent Advances in the Reconstructive Surgery of Major Arterial Lesions, Dr. Robert Linton, Brookline, Mass.
The Role of the Surgeon in Disaster Management, Col. Joseph Schaeffer.

An audio-visual program will be continued each day of the meeting and will include eight films produced by foreign physicians. Alumni meetings, instructional courses, and scientific exhibits are planned. For information write the American Academy of Orthopaedic Surgeons, Inc., Mr. John K. Hart, 116 S. Michigan Ave, Chicago 3, Executive Secretary.

Dr. Horwitz to Succeed Dr. Soper.—Dr. Abraham Horwitz, of Chile, has been elected director of the Pan American Sanitary Bureau, to assume office Feb. 1, 1959, succeeding Dr. Fred L. Soper, whose third four-year term of office ends Jan. 31, 1959. As the Pan American Sanitary Bureau is the Regional Office for the Americas of the World Health Organization, Dr. Horwitz's name will be presented to the executive board of WHO for appointment as the Regional Director for the Americas of that organization. Dr. Horwitz is presently assistant director of the National Health Service of his country, on leave from his position as director of the School of Public Health, University of Chile. From 1950 to 1953 he served in the Pan American Sanitary Bureau's Washington headquarters and was chief of the Professional Education Branch when he resigned to accept his present post in Chile. The Pan American Sanitary Conference meets once every four years to elect the director, to study health problems in the hemisphere, and adopt a program and budget.

Traffic Deaths Continue to Decrease.—The National Safety Council has reported a 1% drop in September traffic deaths from the same month last year.

The traffic death toll for the nation at the end of nine months still was 6% below the same date last year—26,180 in 1958 against 27,770 in 1957. The council estimated that traffic accidents in the first nine months of 1958 also brought disabling injuries to about 900,000 persons. The highway death total for September was 3,300, as compared with 3,330 for September last year. September was the 13th month in a row and the 21st in the last 22 to show a drop in deaths from the same months of the year before. The only lapse came in August, 1957. The downward trend began in December, 1956. Vehicular travel across the nation went up 2% in the first seven months of this year (latest figure available). Traffic deaths went down 7% in the same period. This produced a mileage death rate (number of traffic deaths per 100 million vehicle miles) of 5.1—lowest on record for the first seven months of any year and 9% below the rate of 5.6 for the same period last year.

Surgeons Meeting in Houston.—Physicians are invited to a sectional meeting of the American College of Surgeons in Houston, Texas, Feb. 2-4 at the Shamrock Hilton Hotel. Reports in general surgery, a full day's otolaryngology program, a cancer workshop, and hospital clinics will comprise the three-day meeting. Dr. Jesse G. Heard, Houston, associate professor of surgery, Baylor University, is chairman of the Advisory Committee on Local Arrangements. General sessions will include discussions on tumors, varicose veins, preparation of parents for parenthood, cancer, radiation hazards, diseases of the pancreas, gastrointestinal tract bleeding, and other topics. Dr. Isidor S. Ravdin, chairman, Board of Regents, will act as moderator at the fellowship luncheon discussion on college activities Feb. 3. A motion picture program will be presented the evening of Feb. 2, with Dr. William D. Seybold, Houston, presiding. The Houston Ophthalmological and Otolaryngological Society has collaborated in preparing the otolaryngology program for Feb. 2, Dr. James C. Dickson, presiding. Dr. H. Prather Saunders, associate director, The American College of Surgeons, 40 E. Erie St., Chicago 11, is in charge of all sectional meetings for the college.

Awards in Arthritis and Heart Disease.—The Gairdner Foundation has announced its first international awards in arthritis and heart disease, totaling $40,000. The award of merit has been awarded to Dr. Alfred Blalock and Dr. Helen B. Taussig, of Johns Hopkins University, Baltimore, for their initial development of the "blue-baby operation." Three Gairdner Foundation annual awards of $5,000 each have been given to Dr. Harry M. Rose and Dr. Charles Ragan, of New York City, "for their discovery of the first practical laboratory test for the diagnosis of rheumatoid arthritis"; Prof. W. D. M. Paton and Dr. Eleanor Zaimis, of London, England, "for their discovery of the first drugs to be proven practical and effective in treatment of high blood pressure"; Dr. W. G. Bigelow, of Toronto, Ontario, Canada, "for his development of the technique of hypothermia, or the 'deep freeze' operation for heart surgery." The Foundation's funds derive from gifts of J. A. Gairdner, a Canadian industrialist, and members of his family. Mr. Gairdner was a former President of The Canadian Arthritis and Rheumatism Society from 1949 to 1952 and Chairman of its National Board of Directors from 1952 to 1958. The awards are for achievement and not grants for support of future research. The awards are to be presented at ceremonies to be held in Toronto on May 15-16, 1959, and winners will come to Toronto to participate in scientific meetings arranged in cooperation with the University of Toronto.

Physicians Nominated for Football Honor.—The names of 72 senior football lettermen of the class of 1934, honored by their alma maters with nomination for *Sports Illustrated's* Silver Anniversary All-America, have been submitted to the judges which will name the 25-man roster. Twelve of the nominees have earned distinction in the field of medicine. The annual competition seeks to "emphasize the pursuit of the rounded human values in which athletics and education are joined" through honoring those players who have most distinguished themselves in their chosen fields of life. Only participation by a senior on a 1933 varsity team, not star performance, is the condition of nomination. Doctors nominated this year are:

Wilford L. Cooper, (nominated by Abilene Christian College) head, department of proctology, Lexington, Ky., Clinic; Joseph M. Teta, (Alfred University) general practitioner, Long Island, N. Y.; Frank B. McGlone, (University of Colorado) specialist in gastroenterology; Paul A. Kennedy, (Georgetown University) Buffalo, N. Y., chairman of the Surgical Section of the New York Medical Society; David Eli Kopans, (Harvard University) specialist in gynecology and obstetrics, Boston; Owen B. Murphy, (University of Kentucky) orthopedic surgeon; John V. Prevost, (Lafayette College) former Navy medical officer in private practice in Wellsboro, Pa.; George Linton Wolcott, (Lehigh University) medical director and assistant vice-president of the Bristol-Myers Company, New York City; George F. Parke, (Montana State College) chief of staff of the Centralia, Washington General Hospital; Ray E. Burger, (University of Virginia) physician and surgeon, Welch, W. Va.; Charles H. Brown, (Wesleyan University) professor of medicine and member of staff at Cleveland Clinic Foundation and Cleveland Clinic Hospital; Charles M. Barrett, (Xavier University) professor of radiation therapy, University of Cincinnati.

Society News.—The Central Neuropsychiatric Association has elected the following officers for the current fiscal year: president, Dr. Hamilton F. Ford, Galveston, Texas; president-elect, Dr. Martin H.

Hoffmann, Detroit; vice-president, Dr. Oscar B. Markey, Cleveland; and secretary-treasurer, Dr. Ralph M. Patterson, Columbus, Ohio. The next meeting will be held in New Orleans, Oct. 16-17, 1959.—The following officers were elected at the recent meeting of the **North Central Medical Conference** Oct. 11-12: Dr. Lien O. Simenstad, Osceola, Wis., president-elect for the year 1960; secretary, Mr. Harold W. Brunn, who will become executive secretary of the Minnesota State Medical Association Jan. 1, 1959; secretary-emeritus, R. R. Rosell, who is now executive secretary of the Minnesota State Medical Association and who will retire Dec. 31. President-elect for 1959 is Dr. Arthur J. Offerman, Omaha.—At the interim meeting of the **American Institute of Ultrasonics in Medicine** held Aug. 23 Dr. Jerome W. Gersten, Denver, was elected president and Dr. John H. Aldes, Los Angeles, was elected secretary-treasurer.—Dr. William S. Kroger, clinical associate professor of obstetrics and gynecology, Chicago Medical School, was elected president of the **Academy of Psychosomatic Medicine** at its recent annual meeting in New York City. Other officers are: Dr. Maury D. Sanger, Brooklyn, vice-president; Dr. Bertram B. Moss, Chicago, secretary; Dr. Zale A. Yanof, Toledo, Ohio, treasurer; and Dr. Morris M. Peshkin, New York City, historian. Dr. Wilfred Dorfman, of Brooklyn, as president-elect, will succeed to the presidency at the sixth annual meeting of the academy next October at Cleveland.—Dr. James C. Overall, of Nashville, Tenn., has been elected president of the **American Academy of Pediatrics** for the year ending in October, 1959, and Dr. William W. Belford, of San Diego, Calif., vice-president. The Executive Board members elected for the coming year are: Drs. Richard C. Eley, Boston; George M. Wheatley, New York City; Carl C. Fischer, Philadelphia; William Weston Jr., Columbia, S. C.; James G. Kramer, Akron, Ohio; Harold F. Flanagan, St. Paul, Minn.; Clarence H. Webb, Shreveport, La.; Frank H. Douglass, Seattle; George H. Schade, San Francisco; and Anibal Ariztia, Santiago, Chile.—The **Clinical Orthopaedic Society** has elected the following officers: president, Dr. Atha Thomas, Denver; vice-president, Dr. Robert C. Robertson, Chattanooga, Tenn.; secretary-treasurer, Dr. Charles H. Frantz, Grand Rapids, Mich.; senior member, Dr. Kerwin A. Fischer, Louisville, Ky. (Membership Committee); junior member, Dr. Charles H. Herndon, Cleveland (Membership Committee).

CANADA

Institute for Mentally Ill Accredited.—The Board of Commissioners has approved the recommendation of the American Psychiatric Association that the Albert Prevost Institute, Montreal, be accredited. This is the result of a survey of the premises, a study of the records, and an inspection of all the services made by the inspectors of the Central Inspection Board who published a report to th effect over the signature of Dr. Douglas A. Johnsto The accreditation was granted, the standards bei in conformity with the requirements for an instit tion specialized in the treatment of the mentally i

Surgeons Meet in Vancouver.—Surgeons and relat medical personnel are invited to attend the three-day Sectional Meeting of the American College of Surgeons in Vancouver, British Columbia, Feb. 26-28, 1959. Headquarters will be the Hotel Vancouver. The program will include reports on plastic surgery of the hand, varicose veins, the bad risk surgical patient, athletic injuries, arterial injuries, the control of diagnostic radiology, treatment of breast cancer, surgical treatment of head and neck cancer, and diseases of the pancreas. Symposiums on infections, trauma, and cancer will be presented. Selected medical motion pictures and cine clinic films from the 1958 clinical congress will be shown. Dr. William L. Sloan, Vancouver, will represent the American College of Radiology in his report on Thursday afternoon which is one of a series being presented at each of the 1959 Sectional Meetings of the American College of Surgeons, as a co-operative program between both colleges on the subject of patient exposure from diagnostic x-ray. On Saturday the program will emanate from Vancouver General Hospital. Canadian doctors will present reports on cancer of the thyroid gland, parathyroid tumors, parotid tumors, hip fractures, and frozen sections in surgery. Dr. H. Prather Saunders, Associate Director, the American College of Surgeons, 40 E. Erie St., Chicago 11, is in charge of all sectional meetings for the college.

FOREIGN

Meeting on *Pneumoconioses*.—Experts from 10 countries met recently at the International Labor Organization headquarters, Geneva, Switzerland, on the international classification of radiographs of pneumoconioses. The agenda was opened by Mr. Abbas Ammar, assistant director-general of the International Labor Organization. Prof. Gernez-Rieux, director of the Pasteur Institute at Lille, was elected chairman of the meeting. The experts came from Belgium, France, the Federal Republic of Germany, Italy, Poland, Switzerland, the Union of South Africa, the United Kingdom, the United States, and the U. S. S. R. Representing the U. S. was Dr. Robert H. Flinn, chief, Division of the Health, Bureau of Mines, the Department of the Interior.

CORRECTION

Myocardial Failure in Toxemia of Pregnancy.—In the Dec. 20, 1958, issue of The Journal, page 2191, the sixth word in the 28th line of the Medical Literature Abstract entitled "Myocardial Failure in Toxemia of Pregnancy," should have read "ST" rather than "5T."

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part II only, April 21-22; Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates, Inc.: Stations around the world, Feb. 17. Deadline for foreign applications was Nov. 17. The following examination will be held Sept. 22 with application deadline of June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Alaska:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Written Examination and Reciprocity.* Phoenix, Jan. 14-16. Sec., Dr. Thomas H. Bate, 2910 North 7th Ave., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, June 11-12. Sec., Dr. Joe Verser, Harrisburg.

Connecticut:* *Regular. Examination.* Hartford, March 10-12. Acting Sec., Dr. Louis P. Hastings, 160 St. Ronan St., New Haven. *Homeopathic. Examination.* Derby, Jan. 13. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

Delaware: *Written Examination and Endorsement.* Dover, Jan. 13-15, Jan. 22. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

Florida:* *Examination.* Miami Beach, June 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, June. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Hawaii: *Examination.* Honolulu, Jan. 12-13. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: *Examination and Endorsement.* Boise, Jan. 12-14. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity.* Chicago, Jan. 26-30. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Kansas:* *Examination.* Kansas City, Jan. 16-17. *Reciprocity.* Kansas City, Jan. 14. Sec., Dr. F. J. Nash, 364 New Brotherhood Bldg., Kansas City.

Maine: *Examination.* Portland, March 10-12. *Endorsement.* Portland, March 12. Sec., Dr. Adam P. Leighton, 142 High St., Portland.

Massachusetts: *Examination.* Boston, Jan. 13-16. Sec., Dr. Robert C. Cochrane, State House, Room 37, Boston 33.

Minnesota:* *Examination.* Minneapolis, Jan. 20-22. *Reciprocity.* St. Paul, February. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul.

Missouri: *Examination.* Kansas City, Jan. 9-10. Exec. Sec., Mr. John A. Hailey, Box 4, Jefferson City.

Montana: *Examination and Reciprocity.* Helena, April 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

New Hampshire: *Examination and Endorsement.* Concord, Mar. 11-14. Sec., Dr. Edw. W. Colby, 61 So. State St., Concord.

New Mexico:* *Examination and Reciprocity.* Sante Fe, May 18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New Jersey: *Examination.* Trenton, Jan. 20-23. Sec., Dr. Royal A. Schaaf, 28 W. State St., Trenton.

North Carolina: *Reciprocity.* Southern Pines, Jan. 17. *Examination.* June. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity.* Grand Forks, Jan. 7-10. Sec., Dr. C. J. Glaspel, Grafton.

Oklahoma:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, Jan. 6-7. *Reciprocity.* Portland, Jan. 8-10. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination.* Philadelphia, Jan. 7-10. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Puerto Rico: *Examination and Reciprocity.* San Juan, March 3. Acting Secretary, Dr. Herminio Mendez Herrera, Box 9156, Santurce.

Rhode Island:* *Examination.* Providence, Jan. 8-9. Admin., Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota:* *Examination.* Sioux Falls, Jan. 20-21. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Utah: *Examination.* Salt Lake City, July 8-10. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Washington:* *Examination.* Seattle, Jan. 12-14. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

West Virginia: *Examination and Reciprocity.* Charleston, Jan. 5-7. Sec., Dr. Newman H. Dyer, State Office Bldg. No. 3, Charleston 5.

Wisconsin:* *Examination and Reciprocity.* Madison, Jan. 13-15. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., 1 West Wilson St., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, Feb. 2. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arkansas: *Examination.* Little Rock, May 4-5. Sec., Dr. S. C. Dellinger, University of Arkansas, Fayetteville.

Connecticut: *Examination.* New Haven, Feb. 14. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

Florida: *Examination.* Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

Iowa: *Examination.* Des Moines, Jan. 13. Sec., Dr. Elmer W. Hertel, Wartburg College, Waverly.

Kansas: *Examination.* Kansas City, June. Sec., Dr. L. C. Heckert, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, Feb. 12-13. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., West Michigan Ave., Lansing.

Minnesota: *Examination.* Minneapolis, Jan. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

New Mexico: *Examination.* Santa Fe, Jan. 18. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Mar. 27-28. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Rhode Island: *Examination.* Providence, Feb. 18. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Tennessee: *Examination.* Memphis, Dec. 31-Jan. 1. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

Texas: *Examination.* April 1959. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination.* Seattle, Jan. 7-8. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

---

*Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE

Award of Commendation Medal.—Lieut. Col. Frederick S. Spiegel, M. C., recently was presented the Air Force Commendation medal by the director of professional services in the surgeon general's office. Doctor Spiegel was cited for planning and putting into operation a new procedure for processing of medical examinations for Air Force Academy candidates for the class of 1962 and developing new procedures and establishing additional centers for administration of medical examinations. He is a senior flight surgeon and is board-certified in aviation medicine.

SOCIAL SECURITY

Disability Evaluation.—The Social Security Administration's Medical Advisory Committee has developed, with the cooperation of the medical professions, a sound and workable method of determining disability. This difficult task has been accomplished in a way which does not interfere with doctor-patient relationships. The social security law provides monthly disability insurance payments for disabled persons aged 50 or over and for their dependents. Those who are disabled before reaching 50 years may "freeze" their social security records to prevent their future benefits from being reduced or lost entirely. Under the law, a person is considered disabled if he is unable to do any substantial gainful work, and his condition is expected to continue indefinitely. Under the system worked out for determining whether the disability requirement is met, a person who applies for disability insurance benefits or to have his social security record frozen is first asked to get a statement from his physician. The physician is asked to report clinical findings—the results of medical tests and laboratory examinations. The decision as to whether or not the person is disabled is made by a team of trained people, including a physician, in a state agency. They study not only the medical findings but also the person's education and experience. In most states this team is in the state vocational rehabilitation agency. The state vocational rehabilitation agency also considers the possibility of providing rehabilitation services to the disabled person. Thus the social security disability program has provided a new opportunity for getting more disabled people in touch with rehabilitation agencies. Disability evaluation is not a static process but must keep pace with medical progress, according to Secretary Fleming.

PUBLIC HEALTH SERVICE

Neuropharmacology Research Center.—The new research center for the study of drugs and their use in the treatment of mental illness which was opened Nov. 20 at Saint Elizabeths Hospital, Washington, D. C., will be operated jointly by Saint Elizabeths and the U. S. Public Health Service's National Institute of Mental Health. This clinical research center is being set up in the William A. White Building, which has been adapted to accommodate the research facilities and which houses 350 patients. The center is being equipped for a comprehensive, scientific assessment of the tranquilizing and energizing drugs and their effects on mental function.

Dr. Joel Elkes, National Institute of Mental Health pharmacologist and former chairman, department of experimental psychiatry, University of Birmingham in England, is director of the center.

Dr. Winfred Overholser, superintendent of Saint Elizabeths, said "This program, I believe, holds particular promise not only for Saint Elizabeths but for psychiatry in general. I am confident that this carefully planned research undertaking will bring forth knowledge that will guide us in the use of drugs and from which new effective treatment methods will evolve." Working together on the project will be psychiatrists, psychologists, pharmacologists, biochemists, physiologists, and other research specialists.

Neurologists' Mission to the Soviet Union.—In accord with an agreement between the United States and the Soviet Union to exchange missions in various fields, the National Institute of Neurological Diseases and Blindness is sponsoring a study team of six American scientists who will survey the status of neurology in the Soviet Union. The study team departed for Russia, Nov. 18, and will remain there about 30 days. The members of the mission are Dr. Francis M. Forster, chairman, department of neurology, Wisconsin University School of Medicine; Dr. Nathan Woolsey, research professor of neurophysiology, University of Wisconsin; Dr. Paul I. Yakovlev, professor of neuropathology at Harvard University Medical School; Dr. Louis S. Goodman, professor of pharmacology, Utah University School of Medicine; Dr. Henry W. Woltman, professor of neurology, Mayo Foundation Graduate School; and Dr. Karl Frank, neurophysiologist, National Institute of Neurological Diseases and Blindness, National Institutes of Health. A group of Soviet specialists will make a similar study on neurology in the United States at a later date.

DEATHS

Abbott, Leigh Gates Ⓜ Orleans, Vt.; University of Vermont College of Medicine, Burlington, 1945; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; veteran of World War II; interned at Worcester City Hospital in Worcester, Mass., and served a residency at St. Vincent Hospital in Worcester; captain in the medical reserve corps of the U. S. Army from July 8, 1946 to July 2, 1948; member of the school board; on the staffs of the Broadview General Hospital and Orleans County Memorial Hospital in Newport Oct. 15, aged 35, of coronary thrombosis.

Andress, David Gustavus Ⓜ Madrid, Ala.; Chattanooga (Tenn.) Medical College, 1904; at one time president of the Bank of Madrid; in 1954 was awarded a certificate of merit by the Medical Association of the State of Alabama in recognition of 50 years service as a practicing physician; died Oct. 15, aged 83.

Bailey, Hugh Alvin Ⓜ Charleston, W. Va.; born in Vass, N. C., Dec. 4, 1900; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1928; specialist certified by the American Board of Surgery; member of the Southern Surgical Association and the Southeastern Surgical Congress; fellow of the American College of Surgeons and co-founder and first president of the West Virginia Chapter; consulting surgeon at Memorial, Kanawha Valley, and Staats hospitals in Charleston, and visiting surgeon at Mountain State, St. Francis, and McMillan hospitals; died in a hospital in Baltimore Oct. 25, aged 57, following an operation for cancer of the lung.

Ballard, Robert Jackson, Michigan City, Ind.; Indiana University School of Medicine, Indianapolis, 1942; on the staffs of St. Anthony Hospital in Michigan City, and the Dr. Norman M. Beatty Memorial Hospital in Westville; died July 9, aged 42, of injuries received when his automobile was struck by a train.

Benson, Harry William, Winter Park, Fla.; University of Nebraska College of Medicine, Omaha, 1903; an associate member of the American Medical Association; for nine years a trustee of the Nebraska State Medical Association and in 1952 the organization gave him a distinguished service medal and made him a member emeritus; member of the American Academy of General Practice and one of the founders and past-president of the Nebraska Section; in 1926 was president of the Oakland, Neb., Chamber of Commerce; died in Orlando Oct. 15, aged 82, of thrombosis.

Blackburn, Elisha, Worthington, Ohio; University of Wooster Medical Department, Cleveland, 1903; served as a medical missionary in Africa; died in the Jeanes Hospital, Philadelphia, Oct. 12, aged 85, of arteriosclerosis.

Blankenship, Marvin Winfred Ⓜ Fulton, Ky.; University of Tennessee College of Medicine, Memphis, 1951; interned at the Baptist Memorial Hospital in Memphis, Tenn.; veteran of World War II; co-owner of the Hillview Hospital; accidentally shot and killed by a deer hunter in Grand Junction, Colo., Oct. 17, aged 34.

Bohannan, Hugh Russell Ⓜ Jerseyville, Ill.; Illinois Medical College, Chicago, 1904; past-president of the Jersey County Medical Society; director of the Jersey Savings & Loan Company with which he was associated for over 39 years; died in St. Joseph's Hospital Oct. 20, aged 82, of a cerebrovascular accident.

Boiarsky, Julius Lewis Ⓜ Charleston, W. Va.; Duke University School of Medicine, Durham, N. C., 1935; interned at the Deaconess Hospital in Cincinnati and served a residency at Charleston General Hospital; veteran of World War II; founder and director of the Boiarsky Memorial Hospital; died Oct. 29, aged 51.

Brockway, Porter Bruce Ⓜ Toledo, Ohio; Rush Medical College, Chicago, 1900; member of the House of Delegates of the American Medical Association in 1911; member of the Academy of Medicine of Toledo and Lucas County and the American Public Health Association; veteran of World War I; founder of the health department in the public schools of Toledo, where he served for 33 years as director of health; chief of staff and board member of the Flower Hospital; associated with Toledo Hospital, St. Charles Hospital, and Maumee Valley Hospital, died Oct. 28, aged 83, of coronary insufficiency.

Butterfield, Clarence Egbert Ⓜ Concord, N. H.; Dartmouth Medical School, Hanover, N. H., 1903; on the emeritus staff, Concord Hospital, where he died Oct. 16, aged 82, of coronary thrombosis.

Clark, Harold Chandler, New Rochelle, N. Y.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1918;

Ⓜ Indicates Member of the American Medical Association.

member of the Medical Society of the State of New York and the American Academy of Pediatrics; associated with the New Rochelle Hospital, where he died Oct. 22, aged 65.

Clifton, Willie Mae, Northfield, Ill.; Woman's Medical College of Pennsylvania, Philadelphia, 1932; specialist certified by the American Board of Pediatrics; interned at the Bethesda Hospital in Cincinnati; served a residency at the Children's Memorial Hospital in Chicago, where she was on the attending staff; died in the Evanston (Ill.) Hospital Sept. 27, aged 52, of heart failure due to mitral insufficiency.

Coburn, Henry Clay Jr. ® Brigadier General, U. S. Army, retired, Haddonfield, N. J.; born in Washington, D. C., Aug. 5, 1879; Columbian University Medical Department, Washington, D. C., 1903; entered the medical corps of the U. S. Army in 1909 and saw service in the Philippines and North China from 1910 to 1913; served in France during World War I; chief of medical service at Walter Reed General Hospital, Washington, D. C., from 1935 to 1939, before which he had held similar posts at Fitzsimons General Hospital, Denver, and the U. S. Army Hospital at Fort Sam Houston, Texas; his last active duty assignment before retiring in 1946 was as surgeon at Fort Bragg, N. C.; retired Aug. 31, 1943; retained on active duty until Jan. 20, 1946; held the Legion of Merit and the French Legion of Honor; specialist certified by the American Board of Internal Medicine; service member of the American Medical Association; fellow of the American College of Surgeons and the American College of Physicians; died Oct. 22, aged 79, of coronary thrombosis and arteriosclerosis.

Cochran, Athol ® Joplin, Mo.; Memphis (Tenn.) Hospital Medical College, 1901; member of the Kansas Medical Society; also a minister; formerly practiced in Pratt, Kan., where he was associated with the Ninnescab Hospital; died in the Barton County Memorial Hospital, Lamar, Oct. 19, aged 81, of injuries received in an automobile accident.

Cooley, Ben Hunter ® El Paso, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1921; veteran of World Wars I and II; fellow of the American College of Physicians; past-vice-president of the Texas Heart Association; associated with the Southwestern General and Providence Memorial hospitals and the Hotel Dieu, Sisters' Hospital; died Sept. 20, aged 63.

Cuff, John Reginald, Nashville, Tenn.; Meharry Medical College, Nashville, Tenn., 1926; professor of pathology at his alma mater; certified by the National Board of Medical Examiners; specialist certified by the American Board of Pathology; died in the Hubbard Hospital Oct. 22, aged 64, of cancer of the stomach.

Elkin, Daniel Collier, Lancaster, Ky.; born in Louisville March 26, 1893; Emory University School of Medicine, Atlanta, 1920; served an internship and residency at the Peter Bent Brigham Hospital in Boston, where he became an assistant in surgery at Harvard Medical School; professor emeritus of surgery at his alma mater, where he joined the faculty as instructor of surgery in 1923, subsequently serving as associate in surgery and for 23 years professor and chairman of the department of surgery; in 1939, when it was established, became Joseph Brown Whitehead professor of surgery; visiting professor at the University of Virginia School of Medicine in Charlottesville, University of Michigan Medical School, Ann Arbor, and Harvard Medical School in Boston; chairman, Section on Surgery, General and Abdominal, American Medical Association, from 1944 to 1946; past-president of the American College of Surgeons (of which he was a regent), the Society of Vascular Surgery, Society of Medical Consultants, Southern Surgical Association, American Surgical Association, of which he was past-vice-president, and the Society of Clinical Surgery; member of the International Society of Surgeons, and senior member of the American Association for Thoracic Surgery; member of the founders group of the American Board of Surgery; specialist certified by the Board of Thoracic Surgery; during World War II spent more than three years as chief of the surgical section and chief of professional services at Ashford General Hospital, White Sulphur Springs, W. Va.; released from active duty as a colonel in 1946 and in 1949 was promoted to brigadier general in the reserve; later consultant in surgery to the surgeon general, chief civilian consultant in surgery for the Third Army, and consultant to the Walter Reed Army Medical Center, Washington, D. C.; in 1945 was awarded the Legion of Merit for his Army service in which he "developed and standardized methods of diagnosis and introduced new and improved techniques in surgical procedure on wounds of the blood vessels"; in 1940 he became the third man to be awarded the Matas Medal by Tulane University for "conspicuous achievements in advancing the progress of vascular surgery"; in 1954, at the 104th annual meeting of the Medical Association of Georgia in Macon, received the Lamartine Griffin Hardman award for "distinguished service to the science of medicine and the medical profession in Georgia" and for "exceptional work in the field of vascular surgery"; from 1939 to 1948 surgeon-in-chief of the Grady Memorial Hospital; served as surgeon in chief of the Henrietta Egleston Hospital for Children; member of the founders group of the American Board of Surgery; specialist certified by the Board of Thoracic Surgery; special consultant to the U. S. Public Health Service (National Institutes of Health) and chairman of the subcommittee on vascular surgery of the National Research Council; a member of the committee on medical affairs of Yale University in New Haven, Conn., and a trustee of the University of Kentucky, Lexington; held an honorary doctor of science degree from Northwestern University in Chicago; author of many papers on surgical subjects; died Nov. 3, aged 65, of heart disease.

Grube, Orin Charles, Minneapolis; State University of Iowa College of Medicine, Iowa City, 1957; interned at Broadlawns Polk County Hospital in Des Moines; died in the University Hospitals, Iowa City, Sept. 19, aged 26.

Herbst, Richard Fred Ⓜ Willmar, Minn.; University of Minnesota Medical School, Minneapolis, 1933; on the staffs of the Willmar State Hospital and the Rice Memorial Hospital, where he died Oct. 5, aged 50, of electrolytic imbalance.

Hindman, Sims Seward, Waynesville, N. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; veteran of the Spanish-American War; for many years practiced in Toledo, Ohio, where he was on the staff of the Riverside Hospital; on the staff of the Haywood Hospital; died in the Wyandotte (Mich.) General Hospital Oct. 6, aged 79, of cerebrovascular accident.

Jackson, Isaiah Allen, Richmond, Va.; Leonard Medical School, Medical Department of Shaw University, Raleigh, N. C., 1911; served on the staff of the Richmond Community Hospital, of which he was one of the founders; on the courtesy staff of Richmond Memorial Hospital; died Oct. 28, aged 70.

Jacobson, Arthur Clarence, Brooklyn; born in Brooklyn Sept. 28, 1872; Long Island College Hospital, Brooklyn, 1894; an associate member of the American Medical Association; member of the American Academy of General Practice, American Association for the Advancement of Science, Medical Library Association, Associated Physicians of Long Island, Alumni Association of Brooklyn Hospital and Long Island College Hospital; medical inspector of city schools, department of health, New York City, 1899; physician, department of public welfare, New York City, from 1900 to 1929; physician, department of hospitals, New York City, from 1929 to 1945; author of "Genius–Some Revaluations," published in 1926; in 1927 became editor of the *Medical Times,* serving until he was named editor-in-chief emeritus last January; died in the Brooklyn Hospital Oct. 15, aged 86, of uremia, secondary to arteriosclerotic cardiovascular disease and diverticulitis with abscess and hemorrhage.

Joseph, Cheney Cleveland Ⓜ Baton Rouge, La.; Tulane University School of Medicine, New Orleans, 1938; specialist certified by the American Board of Internal Medicine; member of the American College of Chest Physicians; medical director of the United Security Life Insurance Company; veteran of World War II; on the staffs of Our Lady of the Lake Hospital and the Baton Rouge General Hospital, where he died Oct. 13, aged 44, of an accidental gunshot wound of the brain.

Keating, Robert Alfred Ⓜ Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1937; assistant professor of surgery at his alma mater; fellow of the American College of Surgeons; member of the Columbus Academy of Medicine; veteran of World War II; associated with University, Mount Carmel, Children's, and White Cross hospitals; died in Milwaukee, where he was attending a medical meeting Oct. 7, aged 47, of coronary occlusion.

Kennedy, J. Edward T., Cincinnati; Ohio-Miami Medical College of the University of Cincinnati, 1913; veteran of World War I and was awarded the Belgian Croix de Guerre by the king; for many years police and fire surgeon; formerly associated with the U. S. Public Health Service; served as vice-president of the Good Samaritan Hospital and chief of the medical staff, Deaconess Hospital; rating specialist for the Veterans Administration Hospital; died in the Veterans Administration Hospital Oct. 1, aged 72, of a heart attack.

Manwaring, Ier Jay Ⓜ Norwich, Conn.; Woman's Medical College of Pennsylvania, Philadelphia, 1895; during World War I, as a member of the American Women's Hospital unit number 1, was attached to a division of the French Army and served in France for 14 months; in April, 1919, was decorated by the French government for service at Chateau Thierry and Belleau Wood; died in the William W. Backus Hospital Oct. 3, aged 85.

Martin, Charles Dyer, Davenport, Iowa; Marquette University School of Medicine, Milwaukee, 1917; veteran of World War I; found dead in a hotel room at Chattanooga, Tenn., Oct. 13, aged 65, of heart disease.

Sands, Irving Jesse Ⓜ Brooklyn; born in Russia March 27, 1891; Columbia University College of Physicians and Surgeons, New York City, 1913; served on the faculty of his alma mater; specialist certified by the American Board of Psychiatry and Neurology; fellow of the American College of Physicians, New York Academy of Medicine, and the American Psychiatric Association; member of the American Neurological Association, American Psychoanalytic Association, American Academy of Neurology, American Psychosomatic Society, American Geriatrics Society, and the Association for Research in Nervous and Mental Disease; past-president of the New York Neurological Society; panel psychiatrist for the board of education and honorary police surgeon; consultant for the New York State Workmen's Compensation board; author of "Abnormal Behavior" and "Neuropsychiatry for Nurses"; on the associate editorial board, *New York State Journal of Medicine;* consultant at Veterans Administration; associated with the Rockaway Beach and St. Joseph hospitals in Far Rockaway, Hillside Hospital in Bellerose, New York Neurological Institute of the Columbia-Presbyterian Medical Center in New York City, Adelphi, Brooklyn State, Prospect Heights, Women's, Kingston Avenue, Coney Island, Beth El, and Jewish Chronic Disease hospitals, and the Jewish Hospital, where he was head of the medical board and where he died Oct. 21, aged 67, of myocardial infarction.

Sawyer, Matthias Harvey Ⓜ Ottawa, Ill.; Sioux City (Iowa) College of Medicine, 1904; past-president of the La Salle County Medical Society; at one time health officer of Ottawa; county coroner from 1950 to 1952; on the honorary staff of Ryburn Memorial Hospital, where he died Oct. 13, aged 79, of bronchopneumonia.

Scott, Edwin Laurence, Ocala, Fla.; University of Maryland School of Medicine, Baltimore, 1906; member of the American Orthopaedic Association; formerly practiced in Birmingham, Ala., where he was one of the founders of the Crippled Children's Clinic; recently honored with a citation from the Florida Association of Insurance Agents; died Oct. 10, aged 74, of cancer.

Shaw, Henry Alden Ⓜ Colonel, U. S. Army, retired, Rutland, Mass.; born in New Salem, Mass., June 3, 1867; Harvard Medical School, Boston, 1890; service member of the American Medical Association; fellow of the American College of Surgeons; served an internship at the Massachusetts General Hospital in Boston, then entered the U. S. Army Medical Corps in which he served for thirty years' service before retiring in 1921; decorated with the Distinguished Service Medal; officier, Legion of Honor, France; veteran of World War I; assistant in bacteriology, University of Minnesota Medical School, Minneapolis, 1896-1897; assistant in surgery, Army Medical School, Washington, D. C., 1902-1903; professor of military hygiene, U. S. Military Academy, West Point, N. Y., from 1914 to 1917; sanitary advisor, League of Red Cross Societies Commission to Poland, Warsaw, 1920-1921; in charge of the hospital division of the Veterans Bureau in Washington, D. C., in 1921; psychiatrist and assistant professor of mental hygiene at his alma mater from 1925 to 1934; the following year became psychiatrist in the outpatient department at the New York Hospital; died in the Holden District Hospital, Haydenville, Oct. 19, aged 91.

Shumway, John Raymond, Pleasanton, Kan.; University Medical College of Kansas City, Mo., 1901; served as health officer and coroner of Linn County; on the staff of Mercy Hospital in Fort Scott; died Oct. 1, aged 80, of cerebral hemorrhage.

Southard, Jefferson Sherlock, Fort Smith, Ark.; Tulane University of Louisiana School of Medicine, New Orleans, 1922; veteran of World War I; past-president of the Sebastian County Medical Society; died in Little Rock Oct. 8, aged 63.

Speight, James Ambler, Rocky Mount, N. C.; Tulane University of Louisiana School of Medicine, New Orleans, 1914; member of the Medical Society of the State of North Carolina; formerly county health officer; for services rendered in World War II was awarded a Selective Service Medal; Speight-Stone Clinic is now known as the Memorial Hospital; associated with Park View Hospital; died Oct. 1, aged 68, of heart disease and cirrhosis of the liver.

Stapleton, Harvey Burr Ⓜ Hickman, Neb.; Creighton University School of Medicine, Omaha, 1917; veteran of World War I; member of the American Academy of General Practice; died in Lincoln Oct. 1, aged 68, of coronary thrombosis.

Strode, George King, Whitingham, Vt.; born in Chadds Ford, Pa., Jan. 16, 1886; University of Pennsylvania School of Medicine, Philadelphia, 1912; received master's degree in public health at Harvard in 1927; served as hygienist of the Pennsylvania State Department of Health in Harrisburg; member of the International Health Division of the Rockefeller Foundation since 1920, having been chosen a member for one year in 1916; served as director from 1944 until his retirement in 1951; stationed in Brazil for the division from 1920 to 1926; assistant director from 1927 to 1938 in charge of the division's activities in Europe, Africa, and the Near East, with headquarters in Paris; chairman of the foundation's Paris office from 1932 to 1938, when he became associate director; captain in the medical corps of the U. S. Army, serving in France during World War I; member of the American Red Cross missions during World War II, to Russia in 1941, Iceland in 1942, and North Africa in 1942-1943; during the war was also a member of the advisory council of the division of health and sanitation, of the Institute of Inter-American Affairs, of the subcommittee on tropical diseases on the National Research Council, and of the subcommittee on tropical diseases of the health advisory committee, Office of Foreign and Rehabilitation Operations; an honorary fellow of the Society of Medical Officers of Health of Great Britain; fellow of the American Public Health Association; a member of the American Society of Tropical Medicine, American Academy of Tropical Medicine, of which he was past-vice-president, American Association for the Advancement of Science, and the New York Society of Tropical Medicine; decorated by the governments of Norway, Denmark, Bulgaria, Portugal, France, Rumania, and Sweden; editor of "Yellow Fever," published in 1951; "The Story of the Rockefeller Foundation" by Raymond B. Fosdick published in 1952 praised his work; died in the Brattleboro (Vt.) Memorial Hospital Oct. 27, aged 72, of adenocarcinoma of bladder with metastases.

Sturkey, Edgar Lafayette, Augusta, Ga.; University of Georgia Medical Department, Augusta, 1906; served on the staffs of various Veterans Administration hospitals; died in the Veterans Administration Hospital Oct. 9, aged 76.

Sullivan, Thomas Henry Ⓢ Fall River, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1930; member of the American Academy of General Practice; associate medical examiner for the greater Fall River area; during World War II served as assistant regimental surgeon with the rank of captain in the medical corps of the Second Armored Division; participated in the African campaign and the invasion of Normandy; decorated by the governments of Belgium and the Netherlands and held a presidential citation; died Oct. 12, aged 56.

Sunderland, Paul Ulysses Ⓢ Danbury, Conn.; New York Homeopathic Medical College and Flower Hospital, New York City, 1894; on April 30, 1957, the Connecticut State Medical Society honored him with a 50-year membership citation; on the staff of the Danbury Hospital; died Oct. 9, aged 89, of arteriosclerotic heart disease.

Swartsel, Samuel Carey, San Diego, Calif.; Medical College of Ohio, Cincinnati, 1897; recipient of distinguished service award from the American Cancer Society in 1951; at one time practiced in Cincinnati, where he was past-president of the Cincinnati Medical Society; died Oct. 10, aged 90.

Taylor, Richard Francis, Philadelphia; Jefferson Medical College of Philadelphia, 1905; affiliated with Jefferson and Lankenau hospitals; at one time police surgeon; served on the draft board during World War I; died Oct. 25, aged 79, of heart disease.

Terry, Ernest Alden Jr. Ⓢ Louisville, Ky.; Columbia University College of Physicians and Surgeons, New York City, 1945; certified by the National Board of Medical Examiners; member of the American Academy of Occupational Medicine and the Industrial Medical Association, of which he was counselor; assistant professor of community health, University of Louisville School of Medicine; served in the U. S. Naval Reserve from April, 1946, to April, 1948, and again from September, 1950, to March, 1951; medical director of the General Electric Appliance Park Plant; aged 38; was shot and killed Oct. 26, by a former company employee.

Thomas, Napoleon Roscoe Ⓢ Albany, Ga.; Atlanta School of Medicine, 1913; veteran of World War I; served as chief of obstetrics and chief of staff at the Phoebe Putney Memorial Hospital; died Oct. 2, aged 76, of cerebral thrombosis and arteriosclerosis.

Thompson, Joseph Ignatius A., Margate City, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1904; died Oct. 12, aged 75.

Tucker, Adam Reynold, Raleigh, N. C.; Southern College of Medicine and Surgery, Atlanta, 1912; a founder of the Mary Elizabeth Hospital; died Oct. 19, aged 80, of pneumonia.

Tucker, Augustine Washington, Charlottesville, Va.; born in 1883; University of Virginia Department of Medicine, Charlottesville, 1905; fellow of the American College of Surgeons; professor of surgery at St. John's University in Shanghai, China, where he was associated with St. Luke's Hospital; for many years medical missionary of the Protestant Episcopal Church to China; during World War I served in Siberia with the American Red Cross; at one time superintendent of St. Agnes Hospital in Raleigh, N. C.; from 1950 to 1954 school physician at Woodberry Forest; died in the Blue Ridge Sanatorium Oct. 4, aged 75, of pulmonary tuberculosis.

Warren, Alexander M., Rose City, Mich.; Saginaw (Mich.) Valley Medical College, 1902; died Oct. 6, aged 84, of carcinomatosis.

Watkins, Leon Harlan, Pasadena, Calif.; Johns Hopkins University School of Medicine, Baltimore, 1909; an associate member of the American Medical Association; died Oct. 9, aged 75, of uremia and nephritis.

Watts, Charles Edward Ⓢ Seattle; born in 1889; Rush Medical College, Chicago, 1918; clinical professor of medicine at University of Washington School of Medicine; past-president of the Washington State Medical Association, King County Medical Society, North Pacific Society of Internal Medicine, and the Pacific Inter-Urban Clinical Club; first president of the Washington State Health Council; active in the Washington State Heart Association and served as vice-president of the American Heart Association; fellow of the American College of Physicians, serving on the board of governors from 1935 to 1947 and as vice-president in 1948-1949; during World War II served in the medical corps of the U. S. Naval Reserve; for many years consultant at the U. S. Public Health Service Hospital and the Veterans Administration Hospital; served as chief of medical services at Harborview Hospital; on the staffs of the Maynard Hospital and the Swedish Hospital, where he died Oct. 12, aged 68, of cerebral thrombosis, cerebral arteriosclerosis, and hypertension.

Wiatt, William Slaughter Ⓢ La Jolla, Calif.; Hospital College of Medicine, Louisville, 1897; member of the Missouri State Medical Association; fellow of the American College of Surgeons; served on the faculty of St. Louis University School of Medicine; formerly practiced in St. Louis, where he served on the staff of the Missouri Baptist Hospital; died Oct. 14, aged 86, of cancer of the bladder.

FOREIGN LETTERS

BELGIUM

Iturine.—Delcombe and Devignat (*Annales de la société des sciences médicales*) studied a strain of spore-forming aerobic bacillus which produces in various culture mediums an antibiotic designated as iturine. The bacillus presented all the characteristics of Bacillus subtilis. Two types of colonies isolated differed in their ability to elaborate iturine. The crude products of the cultures could be separated into three fractions. Two of these (O and N) were soluble in acetone, and the third fraction (L) was not. These three fractions were readily differentiated by their antibiotic spectrum, thermostability, and resistance to ultraviolet rays, by paper chromatography, and by dialysis. It is fraction L which has been named iturine. No allergic reaction to this antibiotic has been noted. Clinical tests showed it to be more active than other antifungal agents. About 70% total cures were reported in patients with cutaneous mycoses, with few relapses. Such refractory diseases as epidermophytosis palmaris et plantaris and herpes circinatus have yielded to the drug.

The Postoperative Hiccup.—The postoperative hiccup may appear in different circumstances, and its treatment requires special attention. Reinhold (*Acta anæsthesiologica belgica*) pointed out the harmlessness of the preoperative hiccup, which he treats by aiding respiration. Since the postoperative hiccup is much more alarming, treatment by the inhalation of carbon dioxide infiltration of the phrenic nerve, chlorpromazine, or methamphetamine is recommended. Methamphetamine does not act on the sympathetic nervous system, but rather stimulates the central nervous system. For this reason the author gave 20 mg. of methylphenidate to 12 patients with postoperative hiccup with excellent results in all. The drug was given either intravenously or intramuscularly and no unfavorable side-effects were noted. The action of methylphenidate thus indicates a central origin of hiccups. This drug was especially helpful in old and weak patients in whom chlorpromazine and methamphetamine might cause unfavorable circulatory effects.

Ocular Senescence.—At the 18th International Congress of Ophthalmology in Brussels, Dr. François stated that it was impossible to determine at what age the eye should be considered as being old. Growing old consists of a progressive alteration of the tissular structure, changes that are usually found in the eyes of older persons are considered physiological but those that are found only rarely, although exclusively in the eyes of the aged, are considered pathological. The general senile changes seen in the eye include arteriosclerosis, proliferation of certain tissues, fatty or calcareous infiltration, increase in collagenous tissue, and hyaline degeneration. The degree of these changes varies greatly from one subject to the other and gives no clue to the age of the subject. The sclerotic eye becomes more rigid, and can present a fatty, as well as a calcareous, infiltration. Aging of the lens is associated with a series of changes in its composition, most of which start early in life. In the first years of life, particularly, the concentration of the organic elements become modified, whereas at a more advanced age it is the concentration of the organic substances that changes. Among these latter studies attention was particularly directed toward proteins, which constitute the fundamental substance of the lens fibers.

CANADA

Legal Validity of Breath Tests.—The Supreme Court recently upheld, by a five to three decision, the Saskatchewan provincial legislation compelling suspected drunken drivers to undergo a breath test or face suspension of their driving permit. Mr. Justice Fauteux said that, since a license holder in this condition is in a position similar to that of a person suspected of physical or mental affliction likely to prevent reasonable care and ordinary control of a vehicle, he could be required to submit to an appropriate examination. The refusal to submit to a breath test cannot however be mentioned in court during a charge of drunken or impaired driving, nor can it be made legally compulsory. The main objection to the requirement had been that it conflicted with the criminal code. The three judges in the minority all believed that this was true of the regulation, while the others held that it was not criminal legislation but only a statute relating to the administration and control of the highways.

Experimental Atherosclerosis.—A collaboration between veterinarians and clinicians was described in the *Canadian Medical Association Journal* by Rowsell and co-workers (79:647, 1958). Recent

The items in these letters are contributed by regular correspondents in the various foreign countries.

work suggested that patients with clinical manifestations of atherosclerosis have abnormally active clotting systems. This activity is determined to some extent by the type of fat in the diet. Because butter accelerates clotting in vitro and in vivo, and margarine has little such activity, feeding animals butter could be expected to produce more atherosclerosis than could feeding them margarine. At the Ontario Veterinary College, 33 hogs were divided into three groups and fed a low-fat diet and a diet rich in butter or in margarine respectively. Some atherosclerosis was found in the swine fed a low-fat diet, and this was not greatly increased by adding margarine, but the group fed butter had a marked increase in amount of atherosclerosis. Coagulation indexes at the end of the experiment were most active in the butter-fed swine with the most atherosclerosis. Grossly and microscopically, the atheromas in the swine resembled human lesions.

A further study of coagulation indexes in human subjects by Mustard (*Canad. M. A. J.* 79:736, 1958) produced further evidence linking atherosclerosis with blood coagulation. In this experiment, 135 men were divided into groups of those with clinical complications of atherosclerosis or a family history of the disease and those with no family history and no clinical signs. They were all given a meal of dairy fat and eggs. The atherosclerotic subjects had the greatest mean increase in plasma density and Christmas factor activity, and decrease in antihemophilic globulin activity. The control group had the least changes. It seems that subjects with clinical signs or a family history of atherosclerosis have a more greatly enhanced clotting activity during alimentary lipemia than those with a negative history and no signs.

Alcoholism.—The seminar of the Alcoholism Research Foundation of Ontario included physicians, psychologists, educators, sociologists, psychiatrists, editors, and public relations personnel. It examined the problem of alcoholism almost de novo, asking what the fundamental obstacles were to further understanding of this problem. One of the problems considered was that of setting a threshold above which the regular use of alcohol might be expected to cause harm, either by producing physical or mental impairment or by causing addiction. A forensic expert pointed out the gross discrepancy between the high legal limits for drunkenness (for example, in automobile driving) and the educational limits tacitly admitted in such phrases as "if you drink, don't drive." When the question of substitute addictions for alcohol was discussed, it was doubted whether pharmacologists would ever succeed in producing a harmless drug which could replace alcohol by producing that feeling of self-transcendance some persons apparently need. There appeared to be a number of routes to alcoholism—one person might seek a mystical experience, another a relief from isolation (our herd-approval-seeking society was blamed for much of this), a third oblivion from guilt feelings. The leader of the seminar pointed out that whereas nobody thought that a little tuberculosis or venereal disease was good for one, folklore said that small amounts of alcohol were good for health. Hence the difficulty of getting the public to cooperate in public health campaigns or even to accept the results of research, if the latter conflict with the folklore.

Tissue Culture of Leishmania Donovani.—The School of Hygiene of the University of Toronto may appear a peculiar place to develop a new method of tissue culture of a tropical parasite. The anomaly is explained by the great interest of this school in tissue culture techniques. Leishmania donovani, the cause of visceral leishmaniasis, has proved difficult to grow on tissue cultures for diagnostic work, but Belle (*Canad. M. A. J.* 79:726, 1958) succeeded by using human epithelial cells from amnion trypsinized to liberate the epithelium, grown on nutrient medium, inoculated with cultures of L. donovani grown on Tobie's medium, and incubated. The parasites began to multiply within 48 hours, and continued to grow in culture even after five serial transfers. The author found that the elongated leptomonads multiplied by longitudinal fission, and some became pear-shaped and aflagellate, subsequently undergoing change to ovoid Leishman bodies.

Fluoridation of Water.—Physicians sometimes lose good causes because they will not stand up and fight. Dr. Sturgeon, health officer to an Ontario district (*Canad. J. Pub. Health* 49:425, 1958), told how physicians joined with dentists to obtain the favorable result of a plebiscite taken in the little town of Thorold to determine whether the town should continue to fluoridate its water supply. Led by the local chiropractor, a so-called citizens' committee, composed mainly of out-of-town members and a few religious cranks, had begun an intensive canvass to abolish fluoridation, when the local health forces stepped into the field with a door-to-door canvass by all available nurses, paid advertisements in local papers, public addresses, a total telephone canvass, and talks to students. The vote in favor of fluoridation was 1,359 to 756, and the most important single contribution to success is said to have been the widely distributed letter signed by all the physicians and dentists in the area. Persons with no convictions about the matter often said that the advice of their physician or dentist had outweighed for them the arguments of the opposition. Moreover the widely publicized statement of the American Medical Association on fluoridation did much to counteract the pseudoscientific material put out by the opposition. Special credit should go to one physican who persuaded all his colleagues to put their signatures to the letter which made up the minds of the waverers.

American Academy of Neurological Surgery.—At the meeting of the American Academy of Neurological Surgery in Toronto, in November, T. P. Morley of Toronto said that most cerebral tumor tissue was inherently capable of easier growth than normal adult tissue in culture, but the speed of growth was not related to the degree of anaplasia, and occasionally normal tissue proliferated just as well as the tumor cells. W. J. Horsey of Toronto had inflicted posterior hypothalamic lesions on cats, and used protein-bound iodine (PBI) levels to study thyroid activity afterwards. The PBI levels rose in some cases, though no endocrine changes were seen at autopsy. Presumably there was a disorder of thyroid-stimulating hormone (TSH) secretion. C. Ezrin of Toronto described evidence that there were four normal anterior pituitary cell types, with different staining properties on iron-PAS staining. The alpha, orange-staining cell seemed related to growth hormone and prolactin secretion. The beta, dark-red-staining cell was probably related to a storage form of ACTH and TSH, while the delta cell, staining deep blue, was related to the storage form of luteinizing hormone (LH) and follicle-stimulating hormone (FSH). There was a rather doubtful gamma cell which might contain actively secretory forms of ACTH, TSH, FSH, and LH. In prolonged illness, the delta cells became scarcer in association with a failure of gonadotropic function.

J. W. Scott of Toronto had studied the question of ureteral reflux in dogs, recording bladder and ureteral pressures during increasing bladder distention per urethram. At about 90 mm. Hg pressure in the bladder, urine secretion stopped. At lower levels, intraureteral pressures rose parallel to intravesical pressure, but reflux did not occur. The inference is that in paraplegics it is important to prevent high intravesical pressures from developing. C. G. Drake of London, Ontario, had repaired the facial nerve in three patients by using a graft from the lateral femoral cutaneous nerve of the thigh carried through the posterior fossa. Some return of facial function had occurred. W. M. Lougheed of Toronto had devised a method of introducing blood into the subarachnoid space of dogs through a catheter inserted via a bur hole in the roof of the nose, and was surprised to find that symptoms developed in only 3 of 10 dogs so injected.

S. Birse of Toronto had examined the brains of 19 patients who died after rupture of a berry aneurysm in the anterior cerebral-anterior communicating area. The outstanding finding was that of extensive areas of cerebral softening often detectable only on histological examination, and not at all related to the extent of the subarachnoid hematoma. C. Bertrand of Montreal demonstrated his apparatus for producing needle electrode lesions in the globus pallidus. Lesions 12 mm. in diameter gave durable results as regards reduction of rigidity and tremor in patients with paralysis agitans. To be effective in choreoathetosis, the lesion must be carried further back and involve the corticospinal tract. Murray Falconer of London, England, drew attention to the common association of temporal lobe epilepsy with small focal lesions not detectable even at operation. He had collected 23 cases in which the pathologist had later demonstrated 13 tumors, 2 vascular malformations, 5 cortical scars, and 2 cortical infarcts. Operation had given good results in 21 patients, with complete cure in 14.

INDIA

Determination of Body Fat.—Sen and Banerjee (*Indian Journal of Medical Research*, vol. 46, July, 1958) determined the body fat of 16 men and 9 women by using different methods and compared the results. In the first method, body fat was calculated from the specific gravity of the body determined by the water displacement method according to the formula of Rathbun and Pace. In the second method it was calculated from the density of the body using the formula of Keys and Brozek. The skin fold measurements were taken at different sites by means of calipers over the abdomen, chest, back, and right arm. A high degree of correlation existed between the specific gravity of the body as measured and that calculated from the different skinfold measurements. Thus the skinfold measurements may be used advantageously in place of measurement of the specific gravity of the body by the cumbersome water displacement method. The average fat content of the body calculated from the specific gravity of the body using the first method was 11% of the body weight, while the reading obtained by the second method was 11.3%.

Vaginal Cytology and Uterine Bleeding.—S. J. Kripalani (*Journal of the Association of Medical Women in India*, vol. 46, August, 1958) stated that an abnormality in secretion of hormones is responsible for dysfunctional uterine bleeding. Changes in vaginal smears can indicate the lack or excess of ovarian endocrine functions and the effect of therapeutic hormones. These smears are also helpful in distinguishing dysfunctional bleeding from other causes of uterine bleeding such as abortion or malignancy. The vaginal smears for this purpose should be studied every third or fourth day during the menstrual cycle. The author thus studied 30 women with a clinical diagnosis of functional bleeding. The age of these patients varied from 16 to 45 years; 25 were married, 2 were widows, and 3 were single. Of the married women 11 were nulliparous. The duration of the disease was on an average 2.4 years. Thirteen had prolonged menstrual periods after periods of amenorrhea; 10 had prolonged periods at short intervals of 6 to 18 days; 5 had excessive bleeding at regular intervals of 26 to 30 days; and 2 had almost continuous bleeding with occasional and irregular cessation. Fourteen patients were studied for three or four cycles regularly and showed two main types of curves, 4 showing hyperestrogenic and 10 showing hypoestrogenic curves. Thus the output of estrogen was lower than normal in 10 of these 14 patients with bleeding. In 5 of the 10 patients with hypoestrogenic curves, endometrial biopsy specimens revealed endometrial proliferation with dilated glands in 2, endometrial proliferation without dilated glands in 1, mixed endometrium indicating irregular ripening in 1, and early secretory changes after the patient had been treated with progesterone in 1. A nonhyperplastic proliferative endometrium or a poorly developed secretory phase indicates subnormal ovarian activity and thus the findings of endometrial biopsy specimens and vaginal smears corresponded in these patients.

From the point of view of treatment, patients with functional uterine bleeding were divided into those with hyperestrogenic and those with hypoestrogenic curves. In two patients with hyperestrogenic curves treated with estrogens, bleeding stopped temporarily with recurrence of irregular bleeding, while the cornification percentage showed a further rise but the clinical symptoms persisted. One patient with a hyperestrogenic curve was treated with progesterone but the intensity of bleeding increased and the treatment was stopped. Two patients with the same type of curve were treated with testosterone during the bleeding phase. Good results were seen in both and normal flow at regular intervals was seen during the next three or four cycles. Vaginal smears in the following cycles indicated anovulatory cycles. Two patients with hypoestrogenic curves responded well to treatment with estrogens. Results with progesterone in this type of curve were unsatisfactory. One patient with hypoestrogenic curve was treated with testosterone. An immediate hemostatic effect was produced but the delayed effect was a prolongation of the intermenstrual periods to 40 or more days. The next two menstrual periods were anovulatory and there was hardly any difference in the cornification percentage. Testosterone should thus not be given to patients with hypoestrogenic curves.

Experimental Cataract.—K. Bagchi (*Journal of the Indian Medical Association*, vol. 31, Oct. 1, 1958) stated that the incidence of senile cataract was much higher and its age of onset much lower in countries where protein malnutrition was prevalent. The high incidence and early age of occurrence in India has been explained as possibly due to the effect of sunlight or ultraviolet irradiation. Probably protein malnutrition, which is also widely prevalent here, causes early lens changes. A further insult then in the form of ultraviolet light may precipitate the development of a clinical cataract. To investigate the effect of general protein malnutrition on the lens, the author fed young pigs diets containing 4.5, 6.5, and 10% of protein. Their body weights were recorded and their lenses examined for sulfydryl and glutathione which are decreased in all forms of cataract and precataract conditions. The lens was also examined histologically. The growth rate in all the three groups of animals was found to be much lower than that of control animals that were given a 20% protein diet. The pigs on the lowest protein level showed no increase in body weight. A mature cataract was seen in these animals after about three months. The glutathione and protein-bound sulfydryl contents of the lens (calculated by noting the difference between the total sulfydryl and the glutathione content) were lower as compared to normal. As a result of this reduction, probably the enzymatic activity in the lens is reduced affecting the essential metabolism and leading to lenticular damage.

The biochemical and histological features of these cataractous lenses closely resembled those seen in rat lenses made cataractous by making them deficient in methionine. The pathogenesis of the protein deficiency cataract in pigs may therefore be similar. Thus, although evidence of production of cataract due to protein malnutrition was obtained, no mention of its development in human beings suffering from protein malnutrition has appeared so far in literature. Probably in countries such as India, where protein malnutrition is widespread and cataracts appear at an early age, biochemical changes are produced in the lens in the growing phase as a result of protein deficiency which are not diagnosed by ordinary ophthalmologic examination but may be detected by examination with a slit-lamp microscope. These damaged lenses then develop cataract when further subjected to such factors as ultraviolet light or deficiency of methionine.

Meprobamate and Mental Disease.—Satya and Bhaskaran (*Journal of the Indian Medical Association*, vol. 31, Oct. 1, 1958) treated 27 patients who had various mental disorders with meprobamate given orally, each tablet containing 400 mg. The conditions for which these patients were treated were schizophrenia, catatonic excitement, mania, behavior disorders, anxiety states, alcoholism, and premenstrual tension. The ages of the patients were 19 to 49 years. They were studied for 10 months. Treatment was started with an initial dose of one tablet three times a day. This was gradually increased to six or more tablets a day, the duration of treatment varying from 21 to 181 days. The results were assessed by noting the improvement in the mental condition and reports from occupational therapists, nurses, and social workers.

Results were unsatisfactory in the two patients with catatonic excitement although they were quieter. Fifteen patients with chronic schizophrenia were included in the trial, the duration of illness varying from 3 to 17 years. All these patients had previously undergone a full course of insulin shock, electro-shock, and reserpine or chlorpromazine with no significant benefit. Only three of these improved on treatment with meprobamate. The drug led to sedation without sleepiness and more cooperative behavior but the presenting symptoms did not disappear. Of five patients with manic reaction, one improved but the others showed no change. The drug was of no use in one patient with behavior disorder and mental deficiency. Four patients with psychoneuroses showed marked improvement. Six patients with chronic psychoses who had had no treatment for a long time were given 1.2 Gm. of the drug in a single dose to determine its hypnotic effect. One felt drowsy two hours after the drug was given but was still responsive to verbal stimulation, the effect lasting for about six hours. Others did not feel drowsy but looked more relaxed. Six patients were subjected to routine electroencephalography which was repeated three hours after 1.2 Gm. of the drug was given by mouth. Two days later electroencephalograms were again made three hours after the administration of 75 mg. of chlorpromazine by mouth. No change in the routine record was seen in any patient nor did the brain potentials show the patterns of normal sleep.

SWEDEN

Plea for a Poison Control Center.—Four articles in *Svenska läkartidningen* for Oct. 24 draw attention to Sweden's need for a poison control center. To demonstrate this need, an inventory was taken of the various chemical-technical preparations stocked in 10 homes of physicians and druggists. The 230 such preparations listed could be classified in five groups according to their functions and composition. The preparations in the first group, such as turpentine, were straightforward enough insofar as accurate information about them could be obtained in any standard textbook of toxicology; but many of the other preparations had proprietary names giving no clue to their composition, hence their toxicity when children have swallowed them and it is desired to use the appropriate antidote. In such cases the services of a poison control center possessing all the necessary data would be invaluable to the physician. At the Sachsska Children's Hospital in Stockholm, Dr. Allan Alvin analyzed the 1,026 cases treated by gastric lavage in the period 1953 to 1957. Tobacco was responsible for 44% of these cases and drugs for 24%. Next were chemical-technical preparations (23%), poisonous plants (4%), and the indelible pencil (5%). This pencil contains the relatively nontoxic gentian violet. Pending the creation of a poison control center, Alvin would like to see published an illustrated toxicological botanical map to serve as a guide to the physician called on to treat a case of poisoning by some plant.

Alcoholic Psychoses.—Nilsson and Frey (*Svenska läkartidningen,* Oct. 24, 1958) observed 476 men with delirium tremens at various periods between 1946 and 1957, during which time there was a continuous increase in the incidence of such admissions to the Lillehagens Mental Hospital. The removal of certain restrictions on the sale of alcohol in 1955 must be held responsible for much of this rise, the admission rate for such cases being many times higher in 1957 than in 1946. No favorable effects from cortisone or reserpine were observed, but excellent results were obtained with electroplexy treatment of auditory hallucinations that had lasted over a week. Much was achieved with antibiotics in combating the pulmonary complications, the mortality from which was thus appreciably reduced.

Myocardial Infarction.—If we knew what predisposes to myocardial infarction its prevention and treatment could be greatly facilitated. Forssman and Lindegard (*Svenska läkartidningen,* Oct. 24, 1958) studied 66 men who suffered from this disease. They had survived the infarct by at least two months and most of them by a year. None was older than 55 years, and most were between 45 and 55. For each patient a healthy control of the same age and sex was chosen at random. Among the many criteria by means of which patient and healthy control could be compared were leadership in occupation, mortality from arteriosclerosis under the age of 70 among the parents, height and weight measurements, explosive and moody temperaments, serum cholesterol levels, and the excretion of steroids in the urine. With regard to the two last criteria, it was found that both patients and controls could be grouped in subgroups according as the serum cholesterol level and the excretion of steroids in the urine was high or low. On the whole the patients were characterized by a high serum cholesterol level and a low steroid excretion as compared with the controls. Because so many criteria were invoked in this study, it was difficult to evolve any mathematical formula from them, and the prophylactic measures to be advocated on the base of this material were only tentative.

Arthrosis of Knee.—At an orthopedic hospital in Norrköping, Dr. S. Nilsson (*Svenska läkartidningen,* Oct. 31, 1958) has since 1957 injected hydrocortisone acetate or prednisolone acetate into the knee joint of 48 patients suffering from arthrosis deformans of the knee. Their ages ranged from 40 to 82 (average 62) years. Most of them had previously undergone x-ray treatment six months or more earlier usually with some brief subjective improvement. The disease had lasted 1 to 15 (average 4) years. Under strict asepsis the punctures were made from the side through the suprapatellar bursa, any fluid present being aspirated before the injection was made. No relief of pain was effected during or after the injection by injecting a local anesthetic as practiced in about half the patients. Fifteen complained of transient, relatively intense pain for a few hours after the injections which were given according to two different patterns, either with five after-intervals of four days or with three after-intervals of seven days. With only 10 exceptions, improvement was effected, and this was so great that it amounted to complete disappearance of pain in 14. The results were best in the slight and early cases and in such as were associated with hydrops of the knee. The duration of improvement was also longer for the light than for the severe cases. No great difference could be detected between the action of the hydrocortisone and that of the prednisolone. Both helped to correct extensor defects of the knee in conjunction with prescribed exercises.

UNITED KINGDOM

Neoplasms After Irradiation.—The *British Medical Journal* of Oct. 18 contains three articles on thyroid neoplasms after irradiation. The first is by the staffs of the departments of pharmacology and therapeutics, pathology, and surgery, University of Sheffield, and the Sheffield National Center for Radiotherapy. They reported a series of nine patients with thyroid neoplasms. In all of them the thyroid had been exposed several years previously to ionizing radiation. In seven, indisputable histological evidence of carcinoma of the thyroid was present, and in six, infiltration outside the gland or metastases had occurred. In six the thyroid had been incidentally exposed to irradiation in infancy or childhood during the treatment of cutaneous lesions by radium or x-ray. In them the dose to the thyroid varied from 130 to 2,700 r, and the latent period from 5 to 18 years. The carcinoma developed in the part of the thyroid exposed to the greatest irradiation. The seventh patient was irradiated for the treatment of thyrotoxicosis when she was 26 years old and had an anaplastic carcinoma 37 years later. In two patients a nodular enlargement of the thyroid developed after irradiation. Histologically, hyperplastic adenomatous areas and mitotic figures were seen, but in the absence of local invasion and metastases, the histological features alone did not justify a diagnosis of carcinoma. They were regarded as premalignant conditions. The authors concluded that exposure in childhood predisposes to the appearance of thyroid neoplasms. The association after irradiation in adult life is less certain.

In the second article Dr. A. W. Goolden said that there is little evidence to suggest that the adult thyroid is susceptible to radiation cancer. The development of carcinoma of the thyroid in three patients after irradiation of the neck was reported. Two of the patients received irradiation in adult life. It was probable that the tumors in these three patients were induced by radiation, but it would be necessary to carry out a large-scale survey to find out whether irradiation of the thyroid gland in adult life increased the incidence of thyroid cancer.

An editorial on this subject stated that conclusions based on previous experience with thyroid irradiation must refer to external irradiation by x-rays or radium, but, since the latent period for the development of carcinoma after irradiation in adults is probably at least 20 years, no conclusions can yet be based on any series of patients who have received radioactive iodine, since this isotope has been in clinical use for only about 16 years. Theoretically, owing to the wide variation in the radiation dosage from the absorbed isotope sustained by the thyroid cells at different points, it is certain that some cells surviving damage will have been irradiated with a dose which in other tissues would lead to tumor formation. The risk of the late development of carcinoma in children in particular makes it justifiable only in exceptional circumstances to use radioactive iodine even for diagnostic purposes, or to use x-rays or radium in the neighborhood of the thyroid in the treatment of simple conditions such as thymic enlargement, nevi, and keloid scars. In later adult life the risk of carcinoma is probably of less importance, but further study of it is needed.

Nuffield Bounty.—In the first 15 years of its existence the Nuffield Foundation has given away about $24,000,000. Of this, $18,000,000 has been spent in the United Kingdom and $5,600,000 in the Commonwealth. Science and technology have received $5,000,000, medicine $4,200,000, care of old people and research into aging $2,800,000, and social research and education $3,500,000.

Phonocardiography and Electrocardiography of the Fetus.—Fetal heart rate, rhythm, and waveform were studied by phonocardiography and electrocardiography from the surface of the mother's abdomen by Smyth and Farrow (*Brit. M. J.* 2:1005, 1958). For phonocardiography, which is the most suitable method for recording heart rate and rhythm and for estimating the systolic and diastolic time intervals, the microphone is applied to the point on the abdomen where the heart is best heard. It is not unduly affected by extraneous noises but is by the mother's speech or movement, or by borborygmi. The principal uses of phonocardiography are to monitor the fetal heart and to check regularity of rhythm and rate after version, the giving of drugs such as oxytocin, or surgical induction of labor, and during the induction of anesthesia or forceps delivery. It is also of use in the diagnosis of fetal distress.

Electrocardiography is done by firmly placing on the linea alba the two electrodes, which form the two feet of a metal box containing the preamplifier. A metal belt for the indifferent electrode is placed round the mother's waist between the uterine fundus and the heart. Owing to extraneous disturbances the records of P and T waves are difficult to distinguish with certainty, but the QRS complex can be recorded faithfully in amplitude and duration. If clinical requirements necessitate a full fetal electrocardiogram with P and T waves, as in fetal distress, or before emergency cesarean section, then intrauterine electrodes are passed through the cervical canal, preferably after rupturing the membranes, and their positions ascertained radiographically if necessary. The principal uses of electrocardiography are for the differential diagnosis of pregnancy and multiple pregnancy from tumors; for evidence of fetal life in cases of threatened abortion; for differentiation of breech from cephalic presentation; and to demonstrate the presence of fetal cardiac abnormalities, such as myocardial failure, impeded circulation, and fibrillation. The electrocardiographic diagnosis of heart block normally requires intrauterine electrodes. Records were obtained during electrocardiography which were thought to be due to discharges from the fetal brain. Further improvements in technique are needed before these can be interpreted. They may be artifacts.

"On Call to a Nation".—The British Broadcasting Corporation celebrated the 10th anniversary of the introduction of the National Health Service by televising a documentary film entitled "On Call to a Nation." The film, lasting for 75 minutes, was the longest documentary ever made by the B. B. C. There were no professional actors in it. All the parts were taken by physicians, dentists, and medical personnel working in their usual surroundings in the hospital clinic or in general practice. The film was not intended to show the inner working of the Health Service but rather to show physicians in action and to obtain their views of the Service. Fifty-seven physicians appeared and 25 of them spoke. They included those in urban and rural practice, those with large and small patient lists, those in group practice, and hospital specialists. As payment in general practice is on a per capita basis, it is significant that an urban general practitioner with a large list said that he approved of the Service, while one in a rural area with few patients, who had to travel great distances to see them, did not. Other practitioners and specialists also had various reservations and criticisms to make. A consultant dictating letters at the end of an outpatient session gave his views. Another pointed out the cost of the Health Service to the nation and the public's responsibility for financing it. A pricing bureau was shown dealing with millions of prescriptions to highlight the cost of drugs. The need for increased capital expenditure was emphasized by views of old hospitals and temporary buildings that had long outlived their usefulness. General practitioners were shown seeing their patients. Professional bodies had been consulted, but the planning and direction of the film were done independently.

Poliovirus in Children Under Five Years of Age.—An investigation by the Public Health Laboratory Service showed that about 0.2% of children under 5 years of age are symptomless carriers of poliovirus, the figure rising to 2.5% at the height of an epidemic (*Monthly Bulletin Public Health Laboratory Service,* Oct., 1958, p. 231). The real figure is probably higher than this, as the method of isolating the virus was not entirely satisfactory. The results were based on a survey of 21 areas, both urban and rural, in England and Wales. This carrier rate was found to follow the seasonal curve of poliomyelitis incidence fairly closely at first, but fell off more slowly than that of the reported cases. No clearcut relation between carrier rate and incidence of reported poliomyelitis was found, although there was a rough correlation between the two. The areas studied fell into two groups, with high and low carrier rates respectively. In those with the high carrier rates there were about 50 carriers for every reported case and in the low group the corresponding ratio was about 15:1.

Rockefeller Grant.—The Council of the Royal Society of Medicine announced that the Rockefeller Foundation had offered a grant of $67,370 to the Society for the support of its library over the next five years, while endowments are being sought to ensure its service and maintenance. The library contains 400,000 volumes and nearly 2,000 current periodicals. It is used by more than 60,000 readers annually.

Nobel Prize Winner.—Dr. F. Sanger, head of the Medical Research Council's biochemistry research unit at Cambridge, was awarded the Nobel Prize for Chemistry. After 10 years' research he identified the amino acid constituents of insulin. Four years ago he was made a Fellow of the Royal Society and of King's College, Cambridge.

CORRESPONDENCE

ORGAN PLAYING

To the Editor:—Although the Leisure Corner item in the Oct. 11, 1958, issue of THE JOURNAL, entitled "Playing the Modern Organ" is interesting, two points should be clarified. In the early so-called water organs, the water was not used to create the air pressure to make the pipes speak, but rather was used in the manner of a diving bell to keep the air pressure constant and thus to keep the tone of the pipe in pitch. In the first paragraph of the article, it is stated that the organ is easy to play, and later, that the modern organ is probably the easiest of all instruments to play. If by organ we mean the instrument on which most of the pieces written for organ can be played, it would have to have two or more manuals and 32 pedals. This instrument is not easy to play. Some organ teachers require six years study on the piano before they will permit a student to start on the organ. A person, by reading the Leisure Corner article, might be misled into believing he could play serious organ music without a lot of hard work, which is not true.

MAMMARY CARCINOMA

To the Editor:—I am disturbed by the erroneous impression given by the editorial on mammary carcinoma in THE JOURNAL (168:1228 [Nov. 1] 1958). It would appear from the editorial that the only type of endocrine therapy worth while is surgical removal of either the ovaries, the adrenals, or the pituitary. I believe that this is not only a fallacious impression but is not in the best interest of patients. While the administration of endocrine preparations is mentioned, the editorial states only that the drugs are especially useful in getting patients in better condition for ovariectomy or adrenalectomy and in treating patients with cerebral metastases, hypercalcemia, and lymphedema. I am afraid that many people will be deprived of years of useful remission from hormonal therapy if such treatment is limited to these indications. I agree that ablative therapy is an impressive *tour de force* to the patient, but one cannot ignore the fact that such procedures still work after hormonal preparations have been given and also that, in general, these procedures should not be performed just anywhere by anyone. Adrenalectomy may be technically easier than hypophysectomy, as was pointed out, but it is still an extensive major procedure and the patient is left living a precarious life forever after.

MEDICAL FILM REVIEWS

Machine Mimics Man: The Artificial Kidney: 16 mm., color, sound, showing time 26 minutes. Prepared by Willem J. Kolff, M.D., Cleveland, and George E. Schreiner, M.D., Washington, D. C. Produced in 1958 by Mervin LaRue, Inc., Chicago, for and procurable on loan from Travenol Laboratories, Inc., Division of Baxter Laboratories, Morton Grove, Ill.

By animation and clinical photography this film shows, step by step, the ease of setting up the Travenol Twin-Coil Kidney and the speed with which hemodialysis is available to the patient. Also reviewed are normal kidney function, the basic principles of hemodialysis, and its role in renal insufficiencies and certain systemic poisonings. The important thing about this film is its instructive mechanical aspects for anyone who might be interested in applying this form of therapy. The procedure has gradually been simplified until the Travenol Twin-Coil Kidney seems to offer the most efficient means of hemodialysis available at the present time. The basic principles of hemodialysis and its therapeutic possibilities, in patients with renal insufficiency, especially that which follows systemic poisoning, and other difficulties which call for temporary dialysis, are simplified for quick comprehension. The only criticism to be leveled at this excellent film would be that the explanation of procedure makes it seem almost too simple and might delude some persons into thinking it foolproof. This, of course, is far from the truth, and anyone applying this more or less portable unit should have a thorough basic understanding of the entire subject. The film is highly recommended for showing widely as an educational feature and should be a "must" for any and all newcomers to the field of hemodialysis who are contemplating use of the Travenol Twin-Coil Kidney.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

A Reversible Nephrotic Syndrome Associated with Congestive Heart Failure. W. R. Burack, J. Pryce and J. F. Goodwin. Circulation 18:562-571 (Oct.) 1958 [New York].

A nephrotic syndrome is an unusual and puzzling complication of chronic heart failure. The authors report 4 patients in whom severe proteinuria, hypoproteinemia, massive edema, hypercholesterolemia, and a strikingly abnormal plasma electrophoretic pattern developed in the course of congestive heart failure. The blood urea level was normal or only slightly elevated, and the urinary sediment was normal. Three of the 4 patients recovered from the nephrotic syndrome over a period of 9 months on a regimen of digitalis, low-salt and high-protein diet, and regular, weekly, intramuscular administration of mercurial diuretics. Aminophylline given intravenously just prior to the mercurial was found to enhance the diuretic response.

Reference is made to the little understood but common phenomenon of proteinuria in heart failure. The possible relationship of the proteinuria to the occasional case of nephrotic syndrome is discussed. It is concluded that the nephrotic syndrome occurring in chronic heart failure is not caused by mercurial diuretics and is not in itself a contraindication to their continued use.

The Frequency of Postprimary Pulmonary Tuberculosis According to Pulmonary Arterial Pressure. S.-B. Mattson. Am. Rev. Tuberc. 78:536-546 (Oct.) 1958 [New York].

The author points out that it has been debated for more than a century whether or not certain cardiac valvular defects confer increased resistance to pulmonary tuberculosis. No uniform opinion has been reached. This report describes another attempt to elucidate the question of pulmonary tuberculosis in organic heart disease. The case material for the study was obtained from 2 cardiac clinics in Stockholm, which accept patients from all of Sweden. All cases of congenital cardiac anomaly or of mitral disease in which heart catheterization was performed during the years 1948-1956 were reviewed. The series was confined to persons more than 15 years old. Most of these 413 persons had been referred to the clinics with a view to surgical relief of the cardiac defect. The patients were classified according to the pressure in the pulmonary artery. This pressure was high in 261 patients, normal in 91, and low in 61. Postprimary pulmonary tuberculosis was present in 1% of the hypertensive patients, in 3% of the normotensive group, and in 13% of the hypotensive group. The difference in tuberculosis frequency (10%) between the normotensive and the hypotensive patients was statistically significant. The corresponding difference (12%) between the hypertensive group and the hypotensive group was likewise significant.

Silicotuberculosis: Results of Medical and Combined Medical-Surgical Therapy. C. S. Morrow and M. Kantor. Am. Rev. Tuberc. 78:524-535 (Oct.) 1958 [New York].

The patients studied were hard-coal miners. All were admitted to the hospital between Sept. 10, 1952, and Dec. 1, 1956, and had bacteriological confirmation of the diagnosis of pulmonary tuberculosis. Several sputum specimens contained tubercle bacilli on microscopy and/or culture. All had roentgenographic evidence of silicotuberculosis, had had no previous course of chemotherapy, and were treated continuously with antituberculous drugs for at least a 6-month period in the hospital. Twenty-five patients participated in this study, and all but one satisfied the criteria; in the one exception, the chemotherapy had been interrupted for a relatively short period of time. All but 6 of the patients were between 50 and 70 years of age, and these patients had worked in the mines for about 30 years.

Nineteen of the patients received chemotherapy alone, chiefly streptomycin and isoniazid; the other 6 with unilateral cavitary disease were subjected, in addition, to various thoracic surgical procedures. The results of chemotherapy alone, from the standpoint of cavity closure along with reversal of infectiousness, were poor as compared with those for patients with nonsilicotic tuberculosis. The results of chemotherapy and surgery in the 6 patients were good, particularly with the resectional procedures. If chemotherapy alone is to play a significant role in silicotuberculosis, it would appear advisable to

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. *Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order.* Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

regard conglomerate disease in its initial stages as tuberculous, in the presence of a positive tuberculin test, and to treat it as such if only to prevent further conglomeration.

Local Reactivation of the Primary Tuberculous Focus in the Lung. J. Snijder and T. Vossenaar. Am. Rev. Tuberc. 78:547-564 (Oct.) 1958 [New York].

The primary pulmonary focus has a tendency to a stereotyped course, complications due to inflammation in the regional lymph nodes being fairly frequent, but the pulmonary focus usually subsides and often becomes calcified. In the rare cases in which the primary focus is progressive, 2 types of local extensions occur. 1. Extensions occur before the focus has subsided (type 1). 2. The pulmonary focus becomes reactivated when the primary complex has been quiet for years (often containing calcium), and the patient meanwhile has been considered healthy (type 2). At the "Berg en Bosch" Sanatorium in Bilthoven, The Netherlands, cases of type 2 reactivation were collected. Their rarity is demonstrated by the fact that among 4,554 patients who were discharged from "Berg en Bosch" there were 12 with a local reactivation of an already subsided pulmonary focus; thus, the frequency was about 0.25%. Seven of these patients were less than 15 years old, and the remaining 5 ranged from 15 to 27 years of age. The authors now have under observation a 14-year-old girl with the same condition; thus, a total of 13 instances have been studied.

In 12 of 13 cases the diagnosis could be based on accurate data: in 8 patients the primary complex in its active stage had been recorded on chest films, and in 4 patients a partly calcified primary complex, which had subsided before the onset of the present disease, could be demonstrated from the roentgenograms. In the remaining case the diagnosis was practically certain. Complaints and symptoms were hemoptysis, high temperature accompanied by general malaise, cough, expectoration, fatigue, weakness, and loss of weight. Acceleration of the erythrocyte sedimentation rate and changes in the differential leukocyte count were also observed. Not every patient had all these symptoms, but tubercle bacilli were present in the sputum almost without exception. Depending on the nature and the extent of the liquefaction in the focus, tubercle bacilli in the sputum varied from large numbers seen on microscopy to an occasional one obtained only by culture. The causes of reactivation could not be determined from either the history or the clinical data.

Roentgenographically, the fairly voluminous foci were usually sharply demarcated from the surrounding tissue. The size varied from that of a cherry to that of a chestnut, but one focus was as large as a hen's egg. Nearly all the foci (11 of 13) contained calcium. All foci but one contained a cavity. Except in one case, the cavity was fairly small as compared with the size of the focus. A striking feature was the eccentric position of the cavity, which was invariably situated opposite the calcium deposits. The local extension was accompanied by disseminations, which in the majority of cases were limited to small foci in the immediate surroundings of the large focus. Nine of the foci were localized subpleurally.

The authors regard local reactivation of an initially subsided primary tuberculous pulmonary focus as an indication for a pulmonary resection. The treatment was nonsurgical in only 2 of the patients. In the 11 patients who were operated on, the postoperative course was uneventful, and a satisfactory reexpansion was obtained. All the patients remained in excellent condition after discharge from the sanatorium. Examination of the resected foci showed that they were composed of a small, older portion and a larger, more recent area. The older part consisted of a largely calcified caseous focus. Mycobacterium tuberculosis was exclusively found in the recent area, in the liquefied caseum. In 3 cases, in which the caseous material of the focus was cultured for tubercle bacilli, viable tubercle bacilli were present.

The Effectiveness of Long-Term Treatment of Malignant Hypertension. H. P. Dustan, R. E. Schneckloth, A. C. Corcoran and I. H. Page. Circulation 18:644-651 (Oct.) 1958 [New York].

A majority of patients with hypertension die prematurely, not of hypertension or hypertensive vascular disease as such, but of complications of hypertensive and coronary heart disease, cerebrovascular damage, or some other arterial (not arteriolar) catastrophe. Potent antihypertensive drugs have been in use for 7 or 8 years, but with a lack of information on the relation between the cause of death and the extent of arteriolar damage it is impossible to assess therapeutic gains in terms of prolongation of life or prevention of complications. The situation is quite different in the malignant (accelerated) phase of essential hypertension. The course of this hypertensive syndrome is well characterized, predictable, and relatively brief, with survival of only 10 to 20% of patients for one year. Death is caused primarily by hypertensive arteriolar vascular damage. This is commonly expressed by malignant nephrosclerosis with rapidly progressive renal failure, by intracerebral hematoma, and not infrequently by uncontrollable cardiac failure.

Surveying the courses of 84 patients with malignant hypertension who received treatment with potent antihypertensive agents during the past 7 years, the authors found that 70% survived 1 year of observation; 50%, 3 years; 33%, 5 years; and 26%, 6 years. These survival rates represent substantial therapeutic gains over survival rates in the untreated series of Keith, Wagener, and Barker. The first-year survival rate was weighted by the untoward complication of hexamethonium pneumonitis, and current survival is greater. Other causes of death were rapidly or slowly progressive renal failure and complications of atherosclerosis. The rapidly progressive renal failure was usually associated with poor control of blood pressure. It seemed merely an attenuation of the usual course of malignant hypertension. The syndrome of delayed or slowly progressive renal failure was associated with diffuse occlusive fibrous intimal hyperplasia of major renal arteries. Among the complications of atherosclerosis, cerebral hemorrhage was the most common and was associated with poor control of blood pressure level, while myocardial infarction, the next most common, was not.

It may be that the coronary arteries, like the renal, are subject to progressive occlusive disease in some patients with treated malignant hypertension. It is not clear whether this process represents a continuation in vessels larger than arterioles of a basic vascular disease or a delayed response on the part of the arteries to preexisting severe hypertension. Survival was better in patients who were treated before malignant hypertension had caused extensive vascular damage. Patients who presented themselves for treatment with evidences of severe renal damage generally did not survive for long periods. However, several such have maintained active lives for many months and years. Hence, treatment should be withheld only in the most desperate circumstances.

Temporary Collapse in the Treatment of Pulmonary Tuberculosis. F. T. Rogue. Dis. Chest 34:404-412 (Oct.) 1958 [Chicago].

Rest has generally been accepted as fundamental in the treatment of pulmonary tuberculosis. Tuberculosis sanatoriums were established to provide a haven of rest for those afflicted with the disease as well as to segregate them from the general population. Temporary collapse measures, namely, artificial pneumothorax, pneumoperitoneum, and phrenic nerve paralysis, basically are attempts to secure rest by so-called "splint" or "selective collapse" of diseased lungs. The author reports on the changing status of these temporary collapse measures in the past 10 years at Fitzsimons Army Hospital in Denver and gives his own views based on experiences since 1933. He regards artificial pneumothorax and phrenic nerve paralysis as obsolete procedures. If after adequate use of antituberculous drugs cavitary lesions constitute caseonodular residuals that involve the threat of recurrence, surgical excision is the procedure of choice. Pneumoperitoneum may be used as a last resort in far-advanced cases when, after adequate and prolonged chemotherapy, surgical excision of cavities and/or serious residuals cannot be performed because of serious impairment of pulmonary function. Pneumoperitoneum may be considered also in those rare patients in whom chemotherapy cannot be used because of severe toxicity.

The Effect of Treatment on Mortality Rates in Severe Hypertension: A Comparison of Medical and Surgical Regimens. H. M. Perry Jr. and H. A. Schroeder. A. M. A. Arch. Int. Med. 102:418-425 (Sept.) 1958 [Chicago].

The mortality rates of 209 patients with severe hypertension, treated orally with such a ganglion blocking agent as hexamethonium chloride and with hydralazine hydrochloride, have been compared with the mortality rates reported in the literature as being associated with other antihypertensive regimens, particularly surgical sympathectomy. The comparison was made difficult by the differing criteria used by various authors in grading the severity of the disease prior to therapy. Because effective antihypertensive drugs have been used for a relatively short period, they could be evaluated only in seriously ill patients with significant and predictable mortality rates during the available observation period. This series of previously untreated nonuremic patients, 23 of whom were Negroes, were divided on the basis of their pretreatment status into 2 groups, according to Smithwick's classification; thus, 79 patients were classified as group 3, and 130 as group 4. Their ages ranged from 27 to 70 years, with an average of 49 years. All the patients were followed for 4 years. Of the 130 patients in group 4, 48 had benign hypertension, and 82 were considered to have malignant hypertension, which was associated with azotemia in 35 without evident cardiac failure or any of the common signs of uremia and 47 were nonazotemic. All 82 patients with malignant hypertension had proteinuria and papilledema; 77 had hemorrhagic and exudative retinitis, while 3 had only hemorrhages and 2 only exudates. Each of the 82 patients had a mean supine diastolic pressure of over 130 mm. Hg.

Therapy with the oral administration of hexamethonium chloride and hydralazine hydrochloride was instituted according to a regimen involving an invariant dose of hydralazine plus a variable dose of the ganglion blocking agent 5 or 6 times a day, with the dose of the latter depending on the level of systolic pressure. During the 4 years after the institution of therapy, the mortality was lower in this series of patients treated with a combination of ganglionic blockade and hydralazine than it was in Smithwick's reported series of surgically sympathectomized patients. If the severity of the cardiovascular disease in the group 4 patients was graded on the basis of both hypertensive and atherosclerotic processes, the mortality rate of the patients who were medically treated was 43% and that of the patients who were subjected to operation was 48%. In the nonazotemic patients with malignant hypertension, if classification was based only on the hypertensive process, the mortality rate of the patients who were medically treated was 36% and that of the patients who were operated on was 48%. For all groups of nonazotemic patients who survived the first year of medical treatment with adequately controlled diastolic pressure, the mortality rate approximated 10% during the next 3 years. Mortality was related to race, being noticeably higher among Negroes, but was relatively independent of sex, age, and economic status.

Second Field Evaluation of Bivalent Types 4 and 7 Adenovirus Vaccine. M. R. Hilleman, H. H. Greenberg, M. S. Warfield and others. A. M. A. Arch. Int. Med. 102:428-436 (Sept.) 1958 [Chicago].

A second field evaluation of bivalent types 4 and 7 adenovirus vaccine, prepared by Lederle Laboratories by commercial production procedures, was carried out at Fort Leonard Wood, Mo., during the winter of 1957. The study proved the high degree of efficacy of this vaccine for preventing acute respiratory diseases of different causes in newly recruited soldiers. The incidence of various respiratory diseases was 11.0% among the 2,471 vaccinated subjects and 23.8% among persons of the control group who received a formalin-saline placebo; thus, a reduction of 55% in the attack rates for total respiratory diseases was obtained by the vaccine. The protective effect of the vaccine became evident about 7 days after vaccination. The adenovirus specific attack rates, calculated on the basis of serodiagnostic tests on an approximate 50% sample of cases, were 1.6% in the vaccinated subjects and 16.6% in the control group, and the reduction in cases was 90%. These findings compared favorably with a 98% reduction figure obtained earlier in a study. The complement-fixation test used in this study proved to be a highly reliable diagnostic means of determining whether the respiratory disease was caused by adenovirus even in vaccinated subjects.

Adult civilian groups have shown very low attack rates for adenovirus-caused respiratory disease; therefore, general vaccination of such persons is not justified. There may be a greater need for the vaccine among children and infants. Whether the attack rates in children are sufficiently high to warrant general use of an adenovirus vaccine, what particular types of adenovirus should be included in the vaccine, and whether the vaccine is effective in preventing respiratory diseases caused by adenovirus infection are questions that require further investigation. In taking into consideration the use of adenovirus vaccine in any group of the population, one should bear in mind that this vaccine is ineffective against the common cold.

Production of Hepatic Coma by Carbonic Anhydrase Inhibitors in Patients with Hepatic Cirrhosis. E. Rissel, H. Schnack, N. Stefenelli and F. Wewalka. Schweiz. med. Wchnschr. 88:946-951 (Sept. 27) 1958 (In German) [Basel, Switzerland].

When ascites develops in patients with decompensated cirrhosis of the liver, the removal of water represents one of the most important problems. Among 85 patients with hepatic cirrhosis who were treated with acetazolamide (Diamox), the authors observed 9 patients who had precomatose or comatose episodes. It was found that the comatose attacks that followed the administration of Diamox corresponded to the "ammoniacal encephalopathy" that develops in patients with hepatic cirrhosis either spontaneously or after the administration of ammonium chloride or cation exchange agents that liberate ammonia, after intestinal hemorrhages, or after high-protein diets. The development of the comatose condition is not dependent on the dose of Diamox. As in spontaneous liver coma, the blood ammonia content showed a noticeable increase in all except one patient in whom Diamox had brought on a comatose state.

Frequently the comatose attacks were reversible, but they may also cause death of the patient. In some patients the coma could be counteracted by the intraperitoneal administration of from 200 to 500 cc. of a 10% solution of glutamate. The administration of potassium prior to Diamox treatment prevented the comatose disturbance in only one patient. In most of these 9 patients Diamox failed to exert a diuretic effect. The administration of Diamox was followed by comatose attacks only in patients with advanced hepatic cirrhosis, such as those in whom coma-like attacks had been elicited by other mechanisms. The prognosis was extremely poor in these patients. All except 2 died within 5 months after the first Diamox-induced comatose attack.

The blood ammonia content was investigated in 12 cirrhotic patients in whom Diamox did not cause coma, and it showed no uniform behavior. Simultaneously existing chronic renal diseases exerted no influence on Diamox tolerance. The large majority of patients with hepatic cirrhosis reacted to doses of 250 mg. of Diamox on 3 successive days, or to 125 mg. of Diamox daily for from 2 to 4 weeks, without showing any coma-like disorders. A hypochloremic coma, such as has been observed after the use of mercurial diuretics, was never observed by the authors. They conclude that, if suitable precautions are taken, Diamox can be used even in decompensated patients with cirrhosis and that it has definite advantages over mercurial diuretics.

Selected Aspects of Acute and Chronic Gouty Arthritis: An Internist's Interpretation of an Orthopaedist's Experiences with Gout and Gouty Arthritis. J. H. Talbott. J. Bone & Joint Surg. 40A:994-1002 (Oct.) 1958 [Boston].

The arthritis clinic at the Buffalo General Hospital is especially interested in gout and gouty arthritis and, because of this special interest, has had an opportunity to consider the varied problems of the patient with acute gouty arthritis as well as the patient with chronic tophaceous gout. There are several features of gout and gouty arthritis of particular interest to the orthopedic surgeon. A presumptive diagnosis of acute gout should be entertained in any unexplained acute inflammation of one or more joints, particularly in an adult male. A family history of gout, renal lithiasis, or other ancillary features may be noted. Most important is a clinical description of the acute attack, which displays the cardinal signs of inflammation and may be associated with pyrexia, leukocytosis, and an elevated sedimentation rate. Confirmation of the diagnosis rests upon a prompt response to a full course of colchicine. The level of serum uric acid is not a reliable diagnostic aid. Roentgenographic evidence in the earlier years of the disease is confined to soft-tissue swelling at the time of the acute attacks.

The cause of the acute attack is not known. The pathogenesis of the underlying metabolic disturbance is associated with an increased formation of uric acid by the body. Diminished destruction and impaired excretion by the kidneys as a cause have not been supported by contemporary research. Precipitating factors include surgical intervention, acute infection, emotional trauma, local trauma, and certain drugs, such as penicillin, ergotamine tartrate, vitamin B_{12}, mercurial diuretics, and thiamine hydrochloride, each when administered intravenously. The prognosis in gout is excellent if the prophylactic regimen is followed. This involves the administration of colchicine and a uricosuric agent (probenecid) daily in moderately or severely afflicted patients and less often in those mildly afflicted. If the prophylactic regimen is followed, little or no incapacity needs result.

Deleterious Effect of Intra-articular Hydrocortisone. G. N. Chandler and V. Wright. Lancet 2:661-663 (Sept. 27) 1958 [London].

In a controlled trial of intra-articular steroid therapy in rheumatoid arthritis, both hydrocortisone acetate and hydrocortisone tertiary-butyl acetate were found to give significant clinical improvement lasting several weeks. Four injections of each drug and 4 of placebo were given into the knees over a period of 48 weeks, during which physical grading and functional capacity were measured every 2 weeks. Roentgenograms of the knees were obtained before and after the trial. Both drugs were more effective than the placebo, but despite the generally good clinical response to injections of the hydrocortisone preparations roentgenologic evidence of deterioration, sometimes considerable, was found in the knees of more than half of the patients so treated. Eighteen patients with 25 involved knees completed the trial. Roentgenologic deterioration was observed in 13 joints. Thus, intrasynovial injections of hydrocortisone and related compounds either failed to halt or, more usually, accelerated pathological changes, despite the clinical relief enjoyed by the majority of patients.

This apparent paradox of worsening disease in the face of clinical improvement was subjected to further investigation. No significant association could be traced between the effects of treatment on pain and the range of movement in the 2 groups of patients with and without roentgenologic progression of arthritis. An important difference between the groups was apparent, however, in respect to walking time; a trend toward greater improvement at the 2nd week after treatment in the group with deterioration became very significant at the 6th week. It must be concluded that the principal effect of treatment in this group has been the attainment of a standard performance beyond the capacity of the joint. The discrepancy between the effects on pain and walking time in the 2 groups was probably more apparent than real, for the quantification of pain is notoriously imprecise. The fact that it was not until the 6th week after treatment that improvement in walking time became significant in the group with roentgenologic deterioration suggests that the chief cause for roentgenologic progression was the encouragement of a damaging level of performance by interference with a normal, locally protective mechanism.

A Contribution to the Mycology of the Mouth. E. C. Fox and G. C. Ainsworth. Brit. M. J. 2:826-828 (Oct. 4) 1958 [London].

During recent years particular attention has been paid to mycotic infections of the oral cavity as a complication of antibiotic therapy. In an effort to supply data on the mycology of the mouth in relation to a number of fairly common oral lesions, isolations of fungi were made from patients at Birmingham Dental Hospital during 1952 to 1955 to ascertain whether there were any relationships between fungi and these oral disorders. The isolations were made in the clinic by inoculating slopes of malt extract agar with scrapings taken with a sterile scalpel. Incubation was at 20 to 25 C, and any fungi which developed were obtained in pure culture for identification. Bacteria and actinomycetes were ignored. Twenty-six of 175 patients were excluded from further study, because they had conditions which showed no distinctive mycological findings, such as lichen planus, lupus erythematosus disseminatus, leukoplakia, fungating antrum carcinoma, and dry socket. The remaining 149 patients were grouped as having 6 clinical conditions, namely, angular cheilosis, gingivostomatitis (comprising aphthous, herpetic, acute ulcerative, mycotic, and various stages of inflammatory periodontal conditions), lingua nigra, lingua geographica, coated tongue, and denture sore mouth.

In some persons of the control series (groups of school children, university students, and professional and office workers) isolations were made as in the patients, but in others saliva was sampled by a single swabbing of the tongue, gums, and teeth and by streaking plates or slopes of malt agar with the swab. From the mycological findings in the 149 patients with angular cheilosis, gingivostomatitis, lingua nigra, lingua geographica, coated tongue, and denture sore mouth, it is concluded that Candida albicans seems to play a primary part in the etiology of angular cheilosis and has some connection with the etiology of gingivostomatitis. The diverse fungi associated with the remaining 4 conditions are of uncertain etiological significance.

Rheumatoid Arthritis of the Cervical Spine in the Adult. J. Sharp, D. W. Purser and J. S. Lawrence. Ann. Rheumat. Dis. 17:303-313 (Sept.) 1958 [London].

The authors studied the roentgenologic changes produced in the cervical spine by rheumatoid arthritis in adults, and they also investigated whether such changes may occur as the only evidence of rheumatoid arthritis, that is, without clinical or roentgenologic signs of the disease elsewhere. A series of lateral roentgenograms of the cervical spine from 44 hospital patients, aged 55 to 64 years, who had rheumatoid arthritis were compared with a series from persons of the same age and sex distribution selected at random from the general population. The films from rheumatoid subjects showed more narrowing of the upper cervical disks. This disk narrowing was more often associated with erosion of the vertebral plates and less often with sclerosis or osteophyte formation, and in the apophyseal joints there were more destructive changes. The roentgenograms from nonrheumatoid subjects showed more proliferative changes. In rheumatoid subjects, vertebral subluxations were more frequent and more severe at all levels of the cervical spine.

With the use of these criteria, a series of 428 cervical roentgenograms from random samples of the population were graded for the changes of cervical rheumatoid arthritis. Definite evidence of rheumatoid arthritis was found in the roentgenograms of 6% of the men and 7% of the women. There was a relationship between the roentgenologic grading for rheumatoid arthritis in the cervical spine and a positive sheep-cell agglutination test. There was little or no correlation between these roentgenologic gradings for cervical rheumatoid arthritis and either morning stiffness or a clinical diagnosis of rheumatoid arthritis, or with a diagnosis of rheumatoid arthritis made in accordance with the criteria of the American Rheumatism Association. There was, however, an association between roentgenologic signs of rheumatoid arthritis in the cervical spine and similar signs in the hands and feet. A cervical form of rheumatoid arthritis without peripheral joint involvement may account for an important number of apparently false-positive reactions in the sheep-cell agglutination test.

Clinical-Neurological Study of 21 Cases of Botulism. C. Castedo, M. Hermida and H. Puricelli. Acta neuropsiquiát. argent. 4:118-126 (April-June) 1958 (In Spanish) [Buenos Aires].

An outbreak of botulism in 21 patients who ate canned pimentos in the same restaurant in La Plata, Argentina, between June 2 and 6, 1957, is reported. Toxicity of the suspected food was proved by feeding it to animals. There were 12 fatal and 9 mild cases. The period between ingestion of the toxic food and appearance of symptoms varied between 14 and 48 hours. The early symptoms consisted of nausea, vomiting, dizziness, headache, and asthenia. In patients with severe intoxication, the early symptoms were followed by blurred vision, mydriasis, ptosis, diplopia, strabismus, lack of or delayed pupillary responses, and paralysis of several cranial nerves. In patients with mild intoxication, the predominant symptoms were exclusively oculomotor.

The treatment of these patients consisted of the administration of antibotulinic serum which was specific for types A and B of Clostridium botulinum. The serum was titrated in 2,000 units per cubic centimeter and was administered according to the following scheme: All patients had an intramuscular injection of 10 cc. (20,000 units) of the serum as soon as they reported to the hospital. If ingestion of the toxic food had been moderate and the symptoms abated during a week, a second and final intramuscular injection of the same dose of antibotulinic serum was given, and the patient was discharged. If ingestion of the food had been considerable but the symptoms had diminished after the first injection of antibotulinic serum, the injections were repeated at certain intervals; they were given intramuscularly up to a total dose which varied between 60,000 and 200,000 units. Patients who were hospitalized in a grave condition were given a total dose of 320,000 units of the antibotulinic serum, which was administered as follows: 100,000 units intramuscularly, 200,000 units intravenously, and 20,000 units intrathecally.

Antibotulinic serum therapy was given with the necessary precautions of testing the tolerance of the patients and in association with antihistaminic drugs. Ten of the 12 severely ill patients were treated also with ganglionoplegics and barbiturates as a preliminary to placing them in the pulmotor. Specific antibotulinic serum therapy failed to save the 12 patients who were hospitalized with acute symptoms of severe intoxication. This group included a patient in whom the treatment was started before the appearance of oculomotor symptoms. The botulism toxin seems to block the nonmyelinated endings of the nerve fibrils at the motor plate, inhibiting the production of acetylcholine which controls the neuromuscular synapsis.

SURGERY

Osteogenic Sarcoma of the Jaws and Facial Bones. L. V. Kragh, D. C. Dahlin and J. B. Erich. Am. J. Surg. 96:496-505 (Oct.) 1958 [New York].

The authors report on 9 male and 10 female patients, between the ages of 11 and 60 years, with osteogenic sarcoma of the mandible, on 10 men and 4 women, between the ages of 16 and 62 years, with osteogenic sarcoma of the maxilla, and on 6 men and 5 women, between the ages of 15 and 55 years, with osteogenic carcinoma of the antrum and ethmoid region, who were treated at the Mayo Clinic before March, 1957. Most of the patients were treated surgically with or without adjunctive irradiation therapy. Several patients who received limited surgical treatment elsewhere were cured subsequently by more radical therapy, which consisted of wide surgical resection or diathermy destruction of the lesion and surrounding tissues. Eleven of the 44 patients were still living at the time of follow-up in March, 1957, and in addition 1 patient was known to be alive and well 6 years after treatment. Of the 35 patients treated before March, 1952, 11 are known to have lived for periods ranging from 5 to 28 years after their first definitive treatment at the Mayo Clinic. Six of these had mandibular, 4 had maxillary, and 1 had antral sarcoma. Of these 11 survivors, 5 had chondroblastic, 4 fibroblastic, and 2 osteoblastic osteogenic sarcomas. Neither patient with primarily ethmoidal involvement survived 5 years. Two patients died of recurrent tumor or metastasis 13 and 6 years, respectively, after their first treatment at the Mayo Clinic.

These data show that surgical treatment affords a reasonable chance of cure. A tendency to late systemic spread and a relatively low average degree of malignancy are among the factors that contribute to successful therapy. In the 44 patients symptoms were commonly present and led to many dental and minor surgical procedures before the correct diagnosis was established. This fact emphasizes that a relatively painless nonulcerating mass occurring in the upper or the lower jaw, particularly about an alveolus, should suggest the possibility of osteogenic sarcoma. In the antral and ethmoid regions, early symptoms are lacking. Roentgenographic examination is extremely helpful in most instances, but definitive diagnosis depends on histological studies. In 4 patients the sarcomas arose in regions previously irradiated for benign conditions of bone or soft tissue. More alertness on the part of dentists and physicians would favor earlier correct diagnosis and treatment of osteogenic sarcoma of the jaw.

Considerations and Comparisons of Ligation of the Internal Mammary Arteries: Operation According to the Technique of Davide Fieschi: Experimental Study. C. Zagnoni and P. Ziliotto. Acta chir. italica 14:511-538 (July-Aug.) 1958 (In Italian) [Padua, Italy].

The authors investigated in dogs and in human beings the efficacy of the operation devised by Davide Fieschi for the treatment of coronary insufficiency. This operation consisted of ligation of the internal mammary arteries at the level of the second or the third intercostal space. After ligation a solution of turpentine oil and of ultrafiltered lead tetroxide (minium) was injected into the internal mammary arteries close to their origin, into the coronary arteries, or into the arteries of the pericardium to observe possible passage of the radiopaque substance to the vascular net of the pericardium. At the point of ligation of the internal mammary arteries only a slight and transitory increased blood pressure was observed. However, at the point of ligation a marked increase in the oscillometric rate was noted. It was accompanied by an increased flow into the main collaterals of the ligated artery, which included the pericardium-phrenic vessels. The pericardium-phrenic vessels did not, however, make any significant anastomotic connection with the coronary system. This was observed both in dogs and in human beings. It seemed that the increased flow in the pericardium-phrenic system was a normal and proportional compensation for the interrupted circulation of the main branch. This additional flow into the pericardial system was small and of practically no clinical advantage.

The ultrafiltered minium which was injected into the internal mammary arteries brought into relief the system of the arteries of the pericardium, and it penetrated into the coronary system only through a considerable circumvention. The additional pressure on the coronary system of both humans and dogs with a normal or a defective heart was weak. Likewise, the ultrafiltered minium injected directly into the coronary system of both humans and dogs with a normal or a defective heart spread through many ascending branches of the coronary arteries but did not penetrate into the pericardial system. Consequently, this experiment demonstrated a relative independence of the arterial system of the pericardium from that of the coronary arteries. The authors suggest that for the treatment of coronary insufficiency it is better to apply surgical operations designed to establish a direct vascular connection between the arteries of the pericardium and those of the heart than to resort to ligation of the internal mammary arteries.

Clinical Comparison of Homografts and Braided Nylon in Arterial Bypass Surgery. R. P. Hohf, O. H. Trippel and H. Laufman. A. M. A. Arch. Surg. 77:552-560 (Oct.) 1958 [Chicago].

A group of 33 femoral and iliofemoral homografts were compared with a group of 23 Edwards-Tapp nylon prostheses in a series of 45 patients with bypass procedures. Of 33 homografts inserted, 13 remained patent, and 20 were failures; of the 20 failures, 9 occurred early and 11 late. The 23 nylon prostheses procedures resulted in 10 successes and 13 failures, of which 6 were early and 7 late. Poor distal run-off was considered the cause of 60% of the homograft failures and 54% of the nylon failures. A nylon prosthesis lasted 5 months in an exposed wound, but an exposed homograft softened and ruptured after only 2 weeks. Comparison of the results with homografts and with nylon prostheses in this small series of patients reveals no significant difference in the percentage of successful grafts in the 2 groups. Of the homografts, 39.4% were successful, and of the nylon prostheses, 43.5% were successful. However, a definite difference between the two is that the late failures in the homograft group were occasionally associated with defects developing in the graft itself, whereas late failures in the nylon group were never the result of inherent defects in the prosthesis. There were 5 complications caused by defects peculiar to homografts (3 ruptures and 2 aneurysms), but there were no such defects with nylon tubes.

Homografts, in general, are less durable than plastic tubes. Nylon, as used in this study, has shown no tendency toward weakness for periods up to 2 years. It seems likely that it will outlast the patient in most cases. The ideal prosthesis has not been developed as yet, but the nylon tubes used in this study have eliminated an important cause of graft failures from defects in the structure of the graft itself. Results of bypass surgery are also improved by careful selection of patients, with insertion of grafts only in the most suitable of them.

The Clinical Use of an Elastic Dacron Prosthesis. D. E. Szilagyi, L. C. France, R. F. Smith and J. G. Whitcomb. A. M. A. Arch. Surg. 77:538-551 (Oct.) 1958 [Chicago].

An arterial substitute woven of plain Dacron yarn in the woof and elasticized (Helanca) Dacron yarn in the warp in the form of straight tubes and bifurcations was used in animal experiments and in 43 clinical cases. The prosthesis is elastic, seamless, smooth-walled, finely porous, light, and soft and has the ability to elongate 15 to 20% without deformity. It is easy to procure, store, and sterilize. This prosthesis comes reasonably close to what is required, having a porosity that is satisfactory both from the point of view of arteriogenesis and from that of hemostasis. In animal experiments with long aortic bypass implants, during 11 months of observation the elastic Dacron prostheses showed an excellent rate of patency, even when traversing a tortuous course. Arteriogenesis around the implants was good, and tissue reactivity was low. During 9 months of implantation the initial tensile strength of the prostheses was essentially unchanged.

In considering the results of 9 months' experience with 43 cases, the prejudicial effect of case selection must be kept in mind, as patients with more advanced and diffuse disease were assigned for treatment with angioplastic procedures utilizing the prosthesis rather than for treatment by homograft. In spite of this, the Dacron prosthesis yielded a patency rate only slightly below that obtained with homografts. In angiographic examinations up to 9 months after operation, there was patency of the arterial substitute in 92% of the aortoiliac area grafts and in 63% of the femoropopliteal area grafts. In experiments on dogs there was some evidence that the new-formed lining of the prosthesis was slow to develop. Since the formation of this pseudointima was greatly influenced by the technique of preclotting (which is largely a matter of personal skill), the evidence in this regard was not entirely convincing. Moreover, in older canine specimens the new intima was always found to be satisfactory.

Another factor to be considered in examining results is the initial lack of full familiarity with the technical behavior of a new device. This study shows that results are better when angiographic visualization of the prosthesis is delayed until the 6th postoperative week.

The advantage of plastic prostheses consists in the promise that their rate of deterioration after longer follow-up periods will be much less than that of homografts. If this is true, the late patency rate of plastic implants will be better than that of homografts, since many more of the early good results will persist. The assumption that this is what will happen is supported by excellent experimental evidence but will not be proved until the prostheses have been observed for much longer periods of time.

Scalene Node Biopsy—Clinical Evaluation and Application. S. W. Shapiro and L. T. Palumbo. Am. J. Surg. 96:511-514 (Oct.) 1958 [New York].

The authors performed scalene node biopsies on 51 patients with pulmonary lesions in the department of surgery of the Veterans Administration Hospital in Des Moines, Iowa, in the course of a 30-month period. Metastatic carcinoma in the scalene nodes was found in 9 (18%) of the 51 patients. Thirty-eight of the 51 patients had proved primary carcinoma of the lung, and biopsy of the scalene nodes revealed metastatic carcinoma in 7 patients (19%); 3 of the 7 patients had scalene nodes involved on the right side, and 4 on the left side. Scalene nodes were clinically palpable in 6 of the 38 patients with primary carcinoma of the lung. In 2 patients with palpable nodes, carcinoma was not found on microscopic studies. Of the 4 patients with positive biopsies of the scalene nodes on the left side, 3 had palpable nodes. Lesions of the upper lobe of the left lung accounted for 2 of these, and the third lesion was a left hilar mass. Of the 3 patients from whom positive scalene node biopsies were obtained on the right side, 1 had clinically palpable nodes, and the primary lesion presented as a right hilar mass. There were 3 patients in whom nodes were not palpable clinically, but metastatic carcinoma was found in the scalene node specimens. In the instances of nonpalpable scalene nodes, the incidence of positive nodes thus was 8.1%.

Of the 38 patients with proved primary carcinoma of the lung, 19 were considered to have operable disease and 19 were considered to have inoperable disease; from 2 (10%) of the 19 patients with operable disease, positive scalene node biopsies were obtained. This factor may be an important consideration in selection of patients for exploration and resectability. Scalene node biopsy is an additional adjunct to the establishment of a diagnosis in many lesions and an important aid in the determination and selection of patients with pulmonary lesions for thoracotomy. A properly performed scalene node biopsy should become a definite part of the over-all examination and evaluation of patients with pulmonary lesions, particularly those with primary carcinoma.

Pulmonary Tuberculosis and Gastric Resection. H. Neubert. Tuberkulosearzt 12:444-447 (July) 1958 (In German) [Stuttgart, Germany].

Interrelations between pulmonary tuberculosis and gastric resection were investigated in an extensive literature survey and in studies carried out by the author. Among 4,348 patients who had undergone gastric resection, 120 (2.7%) with pulmonary tuberculosis were found; and among 23,061 patients with pulmonary tuberculosis, 460 (2%) who had undergone gastric resection were found. During the years from 1955 to 1957 at the sanatorium with which the author is connected, 31 patients who had undergone gastric resection were found among 832 male patients with pulmonary tuberculosis (3.5%) In 25 of these patients the tuberculosis became manifest after the operation, while in 6 patients reactivation of the tuberculous process occurred within 4 weeks to 5 years after gastrectomy. Fourteen of the 31 patients required hospital treatment Pulmonary resection had to be resorted to in patients. In view of the fact that in 4 of these patients serious postoperative complications developed, the author believes that pulmonary resection should be performed in gastrectomized patient only when absolutely necessary. It is suggested tha nutritional and vitamin deficiencies, due to defective intestinal absorption after gastrectomy, impai the defense mechanism of the body and thus create favorable conditions for the development of tuberculosis of the lungs.

Ovariectomy and Adrenalectomy for Treatment o Metastatic Cancer of the Breast. J. B. Davis. Am. Surg. 96:492-495 (Oct.) 1958 [New York].

Of 389 women with metastatic cancer of th breast, whose cases were collected from the literature and who had undergone bilateral ovariectom and adrenalectomy for palliation, 189 (48.7%) obtained a remission with reduction of pain, healing of ulcerated lesions as well as of pathological fractures, reduction in size of tumor masses and pleura and peritoneal effusions, and prolongation of usefu life expectancy. Three patients died, an operative mortality rate of 7.9%. The author performed bilateral ovariectomy and adrenalectomy on 11 women, between the ages of 39 and 56 years, with metastatic cancer of the breast. There was a dramatic remission in 9 patients (82%), with no operative death.

Estrogens have been proved to be carcinogenic and have a decided role in the production and maintenance of many cancers of the breast. It can be seen that removal of the ovaries will rid the body of the primary source of estrogen and removal of the adrenals removes all the remaining supply. Bilateral ovariectomy and adrenalectomy are worthwhile operations in the palliative therapy of disseminated cancer of the breast in that they have a low operative mortality rate and prolong the useful life expectancy of nearly 50% of the patients. At present there is no clear-cut criterion useful in selecting patients for adrenalectomy. It seems apparent that any person afflicted with disseminated cancer of the breast should be considered a candidate for this form of therapy.

Hypophysectomy with Yttrium^{90} Implant. C. A. Gleadhill. Irish J. M. Sc. 6:432-433 (Sept.) 1958 [Dublin].

According to Gleadhill, it is difficult to obtain total pituitary removal by either hypophysectomy or implantation of radioactive material, and so he decided to combine the 2 procedures. The radioactive substance used is 8 to 12 mc. of radio yttrium (Y^{90}) in the form of a fine powder. It is a pure beta-emitter and has a half-life of 68 hours and a penetration of about 1 cm. through tissues. When mixing the Y^{90} powder in the operating room with a self-setting acrylic resin proved unsatisfactory, the author tried mixing the powder with bone wax and later with dental impression wax, and this last method has proved consistently satisfactory. The operation is done through the standard frontal pituitary approach. A small skin flap is turned from just above the glabella to just in front of the ear, the bone is burred and sawn, the lower saw-cut being as close to the floor of the anterior fossa as possible, and the bone is left hinged on the temporal muscle. A thick piece of temporal muscle is removed and put aside for later use. When both nerves and chiasma are well displayed, the pituitary stalk is divided. The points of a long-angled forceps are pushed through the aperture in the diaphragma sellae and opened. With the aid of small curettes and pituitary rongeurs, the pituitary gland is removed piecemeal. When removal is believed complete, the plunger is used to force the wax into the apparently empty fossa. A flat spatula is now used to press it in, so that it is fully in contact with the walls of the fossa, and to smooth the upper surface. The piece of temporal muscle previously removed is now laid over the wax, between it and the optic nerves and chiasma, and Gelfoam is laid over the muscle. Since muscle has been used, no visual complications have occurred.

Transverse Incision in Abdominal Surgery of the Colon and Rectum. H. D. Trimpi. Dis. Colon & Rectum 1:339-344 (Sept.-Oct.) 1958 [Philadelphia].

This report concerns 250 consecutive cases of lesions of the colon and rectum in which transverse abdominal incision was employed. There were 151 patients on whom resections for carcinoma were performed. Resections for diverticulitis numbered 43. There were 32 colostomies accompanied by colonoscopic examination for polyps. The remaining 24 operations were performed for Hirschsprung's disease, villous adenomatous polyps, strictures associated with lymphogranuloma venereum and radiation proctitis, and for the purpose of determining whether there was recurrence of malignancy by "second look" operations. Advantages of the transverse abdominal incision, when employed in surgical procedures for lesions of the rectum and colon, are excellent exposure, diminished depth of the wound and easy access to the entire pelvis, less postoperative discomfort, a stronger wound and lower incidence of dehiscence, evisceration, and incisional herniation. Retention sutures, tight taping, and abdominal binders are not required. Early ambulation and deep breathing are facilitated. There is a shorter period of convalescence, and rehabilitation is possible earlier. The final result is a strong narrow scar, which is least displeasing cosmetically.

Carcinoma of the Breast in Middletown, U. S. A. T. C. Moore, D. R. Judd and W. C. Moore. Surg. Gynec. & Obst. 107:433-441 (Oct.) 1958 [Chicago].

The authors report their experience with 307 consecutive cases of histologically verified carcinoma of the female breast studied during a 16-year period, 1935-1951, at the Ball Memorial Hospital in Muncie, Ind. None of the patients were lost to follow-up, and all living patients have been followed for a minimum of 6 years. The Ball Hospital, during the period of this study, was a general hospital of 250 beds and was the only hospital serving Muncie (the "Middletown" of sociological literature), with a population of 60,000, and Delaware County, with a population of 95,000. It provided care for both private and charity patients. Carcinoma of the breast accounted for approximately 10% of the cases of malignant neoplasm handled at this hospital. Although the ages of the patients ranged from 22 to 90 years, 71% were between 40 and 70 years of age. All but 2 of the 307 patients were seen initially at the hospital. Carcinoma was found in the left breast in 160 of the primary cases and in the right breast in 140. Bilateral mammary involvement was encountered in 5 patients.

The Halsted type of radical mastectomy was carried out in 271 of the 305 primary cases (89%). Simple mastectomy was performed in 31 cases, and biopsy only was undertaken in 3. Simple mastectomy was reserved largely for the more elderly patients. The 2 with secondary disease received treatment for local recurrences. All the patients were operated on by specialists in surgery. One hundred ninety-seven of the patients are known to be dead, and 110 are living. Additional primary carcinomas were discovered in 5 of the patients. The 5-year survival of the total group of 307 patients was 54%. The 5-year survival of the 271 patients managed by radical mastectomy was 55%, while that of the smaller simple mastectomy group was 45%. The presence or absence of axillary nodal metastasis was found to be the most important single factor influencing the survival of the patient. Axillary metastasis was encountered in 52% of the patients managed by radical mastectomy. The 5-year survival in this group of patients was 73% without axillary metastasis and only 31% when axillary involvement could be demonstrated.

Radiation therapy, in amounts ranging from 1,800 to 2,000 r, was given after radical mastectomy to 57 patients. There was no apparent improvement in the 5-year survival of the patients who were found to have no axillary metastasis. However, in the group of 104 patients with axillary metastasis who were managed without postoperative radiation therapy, the 5-year survival was 34% as compared with a 53% survival in the relatively small group of 36 patients with axillary involvement who received postoperative radiation therapy. Greater utilization of postoperative radiation therapy in the currently employed 5,500 to 6,000 r range, especially in patients with axillary nodal metastasis, would appear to be worthy of more extensive trial. Ten-year follow-up was obtained in 100% of 184 consecutive patients. Thirty-three per cent of this group were alive 10 years after operation. Radical mastectomy was carried out in 164 of these patients, with a 44% 10-year survival in patients without axillary metastasis and a 22% survival in patients with axillary nodal involvement. The value of 10-year follow-up studies in assessing the results of management of carcinoma of the breast is emphasized.

Adrenalectomy in Cushing's Syndrome: Management and Metabolic Aspects. A. S. Mason, J. E. Richardson and C. E. King. Lancet 2:649-656 (Sept. 27) 1958 [London].

Adrenalectomy should be undertaken only when the diagnosis of adrenal cortical hyperfunction (Cushing's syndrome) is proved beyond doubt. Difficulty may be encountered in adolescent girls who exhibit obesity, acne, pink striae distensae, menstrual irregularity, and even a slight rise in blood pressure. There may be some increase in the urinary metabolites of hydrocortisone, but the absence of muscle wasting and the presence of generalized obesity help to distinguish this condition from Cushing's syndrome. These patients should not be subjected to adrenalectomy, as the disturbance is transitory and responds to a reducing diet. A similar type of benign transient disturbance is sometimes seen in young men. The adrenogenital syndrome in women is more serious. It arises in puberty and continues throughout life. Such patients are plethoric, hirsute, obese yet muscular, with irregular menstruation and, in later years, benign hypertension. Urinary steroid excretion is increased, but this is mainly in the form of 17-ketosteroids. However disfiguring, the disease is not fatal, and therefore adrenalectomy is seldom justified.

Cushing's syndrome, however, is a progressive fatal disease. Studies are reported on 17 patients in whom Cushing's syndrome was associated with adrenal hyperplasia and on 1 patient in whom it was associated with adrenal carcinoma. Special metabolic studies, including nitrogen and potassium balances, were made before operation in 8 patients and after adrenalectomy in 9. Patients were selected for adrenalectomy only when the diagnosis of Cushing's syndrome was beyond doubt and the disease was definitely progressive. Assessment of rate of progress was based on clinical features, such as hypertension, muscle wasting, and weakness, together with the data obtained from metabolic studies of protein catabolism and electrolyte disturbances. There are at present no adequate methods of restoring protein levels. The electrolyte disturbances must be corrected before operation.

Total adrenalectomy is recommended in younger patients and in those with rapidly progressive disease. In older patients subtotal adrenalectomy is preferred. In younger patients the operation is carried out in 1 stage and in older patients in 2 stages. The most important item in the immediate preparation for surgery is administration of sufficient cortisone to maintain the excessive level of glucocorticoids to which the patient has become accustomed. To ensure absorption over the time of operation and during the postoperative period, the cortisone must be given intramuscularly. Intake of water and sodium must be limited in the immediate postoperative period. The dose of cortisone must be gradually reduced, and later the amount of salt increased. The most serious postoperative complication is acute adrenal failure. It should be treated by giving hydrocortisone hemisuccinate, which should always be available in case of emergency. The other complications are ileus, pulmonary embolism, hemothorax, and pneumothorax.

Lobectomy for Postpneumonic Lung Abscess in Infancy and Childhood. T. C. Moore. Surgery 44:741-751 (Oct.) 1958 [St. Louis].

The author reports on 2 infants, a 7-week-old boy and a 16-month-old girl, and on a 9-year-old girl who were subjected to 4 lobectomies for lung abscess. In the 7-week-old infant emergency lobectomy was necessary because of tension pneumothorax due to communication of the abscess with both the tracheobronchial tree and the pleural space. A second, noncommunicating lung abscess occurred in this infant one month after the first operation and was also successfully managed by lobectomy. In all 3 patients the abscess was postpneumonic, and in all it appeared to be caused by Staphylococcus pyogenes var. aureus. The causative agent was cultured from the respiratory tract in all 3 patients and from the contents of 3 of the 4 abscess cavities. No growth could be obtained from the contents of one cavity after 5 weeks of intensive antibiotic therapy. All the abscess cavities were quite large, and all were lined with granulation and fibrous tissue. A communication with the tracheobronchial tree was observed only in the infant boy. The initial symptoms in all 3 patients were of respiratory tract infection with fever of 2 to 4 weeks' duration before admission to hospital. In none of the patients was there any discharge of purulent material from the tracheobronchial tree before the operation. The lung abscess occurred during the Asian influenza epidemic of late 1957 and early 1958 in the 2 female patients; in both, bilateral pneumonitis had been shown by the chest roentgenograms before the formation of the abscess. The cases of these 2 patients were characterized initially by remissions and exacerbations of respiratory tract infection and attacks of marked hyperpyrexia. Lung abscess, particularly of the postpneumonic type, rarely occurs in infancy and childhood. The 2 infants in whom pulmonary resection for lung abscess was required were the only ones on an active pediatric surgical service during an 11-year period (1947-1958) at the Indiana University Medical Center in Indianapolis.

Digital and Instrumental Commissurotomy in Mitral Stenosis: A Study of 2,000 Cases. A. M. Dogliotti, A. Actis-Dato and R. Gentilli. Surgery 44:706-717 (Oct.) 1958 [St. Louis].

The authors report on 2,000 patients who underwent mitral commissurotomy at the clinic for cardiac surgery of the University in Turin, Italy, between 1951 and 1957. Of the 2,000 patients, 987 were operated on by digital splitting only of the commissures; in 556 patients both commissures yielded, in 413 only the anterior yielded, and in 18 only the posterior did. Instrumental commissurotomy only was performed on 396 patients; in 112 patients both commissures were incised; in 248 only the anterior, and in 36 only the posterior. A combined technique was used in the remaining 617 patients; in 395 of them finger fracture and instrumental valvulotomy was applied to both commissures, while in the other 222 one commissure was split by digital fracture only and the other by instrumental valvulotomy only. In general, the anterior commissure was the most frequently divided, whether by finger fracture or by instrumental incision.

In the first 1,000 patients operated on, the enlargement of the mitral orifice obtained by the intervention was smaller than in the next 1,000 patients operated on. With more knowledge of the pathological anatomy of the mitral valve and more experience with the techniques of commissurotomy, greater enlargement of the mitral orifice was obtained. The greater the enlargement, the better was the functional result. Therefore, the authors attempted to enlarge the mitral orifice to a surface size as near to normal as possible. Minimal or moderate mitral insufficiency was recognized at the time of digital exploration of the mitral valve in 276 patients; it remained unchanged postoperatively in most of them; it diminished or disappeared in 29, and it increased in 53. In 36 patients an insufficiency of variable degree was created. Lacerations including the whole atrial wall occurred in 3 patients, and lacerations limited to the point of insertion of the left auricular appendage into the left auricle occurred in 54. All the lacerations, except 2, occurred during digital splitting maneuvers. There were 61 operative deaths (3.05%); of the 61 deaths, 20 (4%) occurred among the first 500 patients, 19 (3.8%) among the second 500, 15 (3%) among the third 500, and 7 (1.4%) among the fourth 500 patients operated on. Of 1,210 patients with elastic valves, death occurred in 30 (2.48%). Of 335 patients with calcified valves, death occurred in 19 (5.67%). Of 455 patients with sclerotic valves, death occurred in 12 (2.87%). Thus, the over-all mortality was lowest in the group of patients with elastic valves and highest in those with calcified valves.

The results obtained with instrumental commissurotomy, either as the sole technique or associated with digital pressure, were definitely better than those obtained with the single finger fracture technique because of the better functional mobility obtained and also because of the lower incidence of complications. There were no particular differences in the mortality rate according to the techniques employed; the mortality seemed to be more related to the anatomic condition of the stenotic valve. Instrumental valvulotomy is not always necessary, but it is suggested in the presence of sclerotic commissures resistant to digital pressure and extensive calcifications of the commissures. It is a safe procedure. For restoration of maximal cusp mobility one should attempt to extend the incision of the commissure up to the optimal limit which is represented by the fibrous ring. The Dogliotti valvulotome proved to be the simplest instrument and the easiest to handle.

Use of Nylon Bifurcation Grafts in Arteriosclerosis. L. D. Hill, G. H. Lawrence and L. Annest. West. J. Surg. 66:276-281 (Sept.-Oct.) 1958 [Portland].

One of the most effective methods of treating aneurysms or obliterative arteritis of arteriosclerotic origin affecting the abdominal aorta and its bifurcation is either the resection of the diseased segment and its replacement by a bifurcation graft or a complete bypass of the obstruction by a graft. Attempts have been made to overcome the difficulty of obtaining and preparing satisfactory homologous arterial grafts by the use of various synthetic materials. One of the most recent and, in the authors' experience, most satisfactory types of grafts has been the Edwards-Tapp nylon graft. This is a braided nylon, Silicone-treated, bifurcation graft which is seamless and has crimped tubing to prevent wrinkling in the iliac branches. The seamless construction does away with the possibility both of leakage through a broken-down seam and of thrombosis in the seams in the smaller branches. Branches of crimped tubing can be bent to form a side-to-end anastomosis without kinking, and in grafts below the inguinal ligament, the crimping prevents thrombosis from occurring when the hip is bent. One disadvantage of the nylon graft, on the other hand, is the fact that it is porous and begins to leak as soon as the clamps are released from the aorta. This disadvantage can be offset, however, and the blood loss can be minimized if the graft is preclotted before it is put in place. Another slight disadvantage is the fact that the ends of the nylon graft must be cauterized in order to keep them from fraying when they are sewed in place. Even after being cauterized, the graft tends to fray at the end unless it is handled very carefully.

Failure of the graft itself did not occur in any of the 20 patients in the authors' series, 12 of whom had occlusive disease and the other 8, aneurysms. One of the patients with occlusive disease died, 9 had excellent results, and in 2 claudication, though not eliminated, was considerably lessened. Two patients had ruptured aneurysms. One recovered and is now working at his previous job without symptoms, although he suffered a myocardial infarction during the postoperative period. The second patient underwent a successful resection and graft of the ruptured vessel, but thrombosis of the right posterior tibial artery appeared and made it necessary to perform an arteriotomy on the first postoperative day. This procedure was also successful, but on the 7th postoperative day the patient died of a pulmonary embolism. One other patient, who was operated on for an aneurysm, died 8 months after the original operation when a second intervention became necessary because of a leak in the proximal anastomosis. It is true this represented failure of a suture line, but it did not represent failure of the graft, because it appeared that the aorta had become necrotic proximal to the anastomosis. Follow-up of the surviving patients with aneurysms showed them to be in good health and without symptoms referable to the arterial tree.

The Effects of Hypophysectomy on Intellectual Functioning. M. Schon. J. Ment. Sc. 103:743-748 (July) 1958 [London].

When hypophysectomy was first employed, it was speculated that patients undergoing this type of surgery might become intellectually so deteriorated that the benefit of the prolongation of the life span might be offset by the possible mental incapacity. In addition, most of the patients who were faced with this type of surgery raised the question as to the possibility of mental deterioration after hypophysectomy. These considerations gave impetus to the present study. Hypophysectomy involves 2 variables: brain surgery, and the elimination of the major source of endocrine stimulation and hormone production. On the basis of literature reports, it was hypothesized that hypophysectomy will not effect any significant changes in intellectual functioning, nor that it will result in brain damage.

Twenty women, ranging in age from 40 to 66 years, who had metastatic malignant breast tumors suspected to be dependent upon endocrine gland factors were studied before and after hypophysectomy. All the patients were tested with the Wechsler-Bellevue Intelligence Scale preoperatively and 6 to 10 weeks postoperatively. The Wechsler-Bellevue Intelligence Scale consists of a verbal scale and a performance scale. No statistically significant change in general intellectual functioning and no brain damage, as measured by the tests, could be noted after hypophysectomy. Thus, the hypothesis was confirmed. There was an increase in accuracy, possibly as a result of postoperative improvement in health or due to the practice effect involved in retesting, and a decrease of speed, probably related to a secondary hypothyroidism because of a deficiency of pituitary hormones.

Congenital Cystic Dilatation of the Common Bile Duct: Special Reference to Radiographic Studies. M. M. Ravitch and G. B. Snyder. Surgery 44:752-765 (Oct.) 1958 [St. Louis].

The authors report 3 cases of choledochal cyst, or congenital cystic dilatation of the common bile duct, in a 3½-month-old female infant and in 2 girls, aged 5 and 13 years respectively. The infant had jaundice since the third week of life and a huge choledochal cyst, for which she was successfully treated by a Roux-Y anastomosis of cyst and jejunum. The 5-year-old girl, with attacks of pain, jaundice, and a palpable mass in the right upper quadrant of the abdomen, had a largely retroduodenal cyst, which was anastomosed to the duodenum with relief of symptoms. In the 13-year-old girl with repeated attacks of violent epigastric pain but without a palpable mass or jaundice, the choledochal cyst was shown preoperatively by an oral cholecystogram, and an intravenous cholangiogram made before the operation confirmed the findings of the cholecystogram. At surgical intervention the cyst was demonstrated clearly by 10 cc. of a 50% solution of diatrizoate (Hypaque) sodium injected into the gallbladder. Two additional injections of 10 cc. and 5 cc. of the contrast medium showed the hepatic and common ducts and also the pancreatic duct. The last injection of the contrast medium was discontinued when resistance was noted, and the gallbladder was seen to be tense for the first time. A precipitous fall occurred in the patient's arterial pressure from 110 to 50 mm. Hg, but withdrawal of 20 cc. of thin bile-colored fluid from the cyst resulted in immediate restoration of normal arterial pressure. A cystoduodenostomy gave relief, but clinical pancreatitis resulted from the injection of the contrast medium in an attack simulating the preoperative attacks. The patient's subsequent course was smooth, and she has remained well for 5 postoperative months.

The diagnosis of choledochal cyst can usually be made on the clinical grounds of recurrent pain and jaundice and a palpable abdominal mass and can occasionally be confirmed by preoperative roentgenographic studies. The diagnosis may be made with absolute precision at surgical intervention by the injection of contrast medium into the gallbladder. The nature and cause of the anomaly remain uncertain. The facts that jaundice eventually supervenes, even though characteristically intermittent, and that dilatation of the hepatic ducts was observed in all 3 patients and was described in other cases collected from the literature indicate an obstructive element. The acute pancreatitis, which was inadvertently produced in the third patient by retrograde injection of the contrast medium under pressure, precisely duplicating her preoperative attacks of pain, made it obvious that injections of contrast medium into the cyst in these patients should be done under gravity with little or no pressure. The small, or largely retroduodenal, cyst should be treated by direct anastomosis between the duodenum and the cyst, and the larger cyst by a Roux-Y anastomosis to the jejunum.

Carcinomatous Degeneration of Pilonidal Cysts: Report of a Case. J. G. Matt. Dis. Colon & Rectum 1:353-355 (Sept.-Oct.) 1958 [Philadelphia].

In an 18-year-old youth who complained of pain and bleeding from the rectum, several pinpoint openings were discovered over the sacrococcygeal junction. A diagnosis of pilonidal cyst with perirectal fistula was made, and the cyst and its ramifications were excised and the wound marsupialized. The pathologist diagnosed a mixed basal-cell and squamous-cell carcinoma of the perianal skin and of the pilonidal sinus tract. One month later, the entire scar and the granulating area were excised en bloc, including a generous cuff of normal tissue on all sides and extending down to the periosteum and the gluteus maximus muscle and into the ischiorectal fat. Marsupialization of the wound was again performed. *Microscopic examination of the specimen revealed no evidence of neoplasia.*

The author considers it remarkable that a lesion as common as pilonidal cyst (which, moreover, may be the result of embryologic vagary or of cicatrix formation [both have been mentioned as precursors of malignancy]) should become involved by malignant degeneration so infrequently. It was suggested by Hall and Lee that failure to detect cancer more often in specimens of pilonidal disease may be owing to inadequate microscopic examination. The author believes that *pilonidal disease, with chronic* drainage or recurrent acute inflammation, requires a surgical procedure that will completely eradicate all involved tissue and that this tissue should be submitted to a histological examination.

The Surgical Patient: Oral Bouillon Feedings. H. B. Benjamin, M. Wagner, N. L. Bugarin and G. Bartenbach. J. Internat. Coll. Surgeons 30:405-411 (Oct.) 1958 [Chicago].

It is now common practice to use the vascular system for alimentation during the postoperative period. To maintain the surgical patient in the ideal state of protein and electrolyte balance requires a great deal of cooperative work among the surgeon, the nurses, and the laboratory staff. If any one of the persons concerned with this program fails to meet his or her obligation, or if a bottle of urine or material obtained by gastric suction is spilled, the entire venture fails. Add to this the great financial burden placed on the patient, and the result is a cumbersome program of scant value to the patient. The numerous phlebotomies and the intravenous administration of massive quantities of fluids was presented by Bailey as the cause of many so-called undiagnosed, or falsely diagnosed, deaths that have been ascribed to the surgical procedure but that are actually due to air emboli. The intravenous infusion of nutritional fluids does not guarantee that the body has accepted and utilized them. Far more stress is placed on keeping the patient in electrolyte and nitrogen balance by intravenous infusions after an operation than is necessary or advisable.

A simple approach would be to administer orally some liquid form of food that would be well tolerated and appetizing and would supply the electrolyte and protein needs of the patient. Beef bouillon broth was selected as being the substance most aptly filling these requirements. Several types of bouillon cubes were tested, and the one selected contained 26.2% of protein, 6.6% of fat, and 10.3% of other organic matter. Two cubes were dissolved in 300 cc. of hot water, and this was given to the patient every 3 hours, starting on the first postoperative day. This broth was well tolerated and induced and increased the appetites of patients; at the same time, the hot fluid encouraged intestinal *peristalsis. A comparative study* was made on patients, most of whom had undergone total or partial gastric resection. Their ages ranged from 30 to 75 years. Blood was drawn on the day the patient entered the hospital for chemical tests; this supplied preoperative blood levels for comparison. Bouillon broth was ordered on the first postoperative day and successive days until the patient was ready for discharge from the hospital. By comparison with patients who received electrolyte therapy parenterally, the administration of bouillon by mouth provided and maintained the same, or better, electrolyte and protein blood levels as did the electrolyte parenteral program. It is not meant to imply that the bouillon feedings are the answer to all problems of postoperative nutrition, but in the opinion of these authors they have several advantages over intravenous feeding and can be a simple and inexpensive approach to a great many nutritional problems of postoperative care.

GYNECOLOGY & OBSTETRICS

Pregnancy After Pneumonectomy for Pulmonary Tuberculosis: Analysis of a Collected Series of Seventy-four Pregnancies in the Netherlands. C. D. Laros. Am. Rev. Tuberc. 78:563-569 (Oct.) 1958 [New York].

Young women who have undergone pneumonectomy often ask their physicians, "Is it sensible to marry, and is there any objection to having children?" To obtain some insight into this problem, a survey was made of the frequency and course of pregnancy in female patients after pneumonectomy for pulmonary tuberculosis. Inquiry produced data on 64 patients from all parts of The Netherlands who had a total of 74 pregnancies. Generally speaking, no adverse effects of the operation for either the mother or the child were seen during pregnancy and labor.

Topical Androgenic Hormones in Vulvar Kraurosis-Leukoplakia Syndrome: Preliminary Report. A. C. Richardson and G. A. Williams. Am. J. Obst. & Gynec. 76:791-799 (Oct.) 1958 [St. Louis].

The authors present a preliminary report on 25 women, their ages ranging from 25 to 89 years, with kraurosis and/or leukoplakia of the vulva, who have been treated primarily with topical testosterone propionate in sesame oil in a petrolatum base. Three patients were referred from charity clinics, and the remaining 22 were private patients. Twenty-four of the 25 patients were, or had been, married and, of these, 19 were parous. Nineteen of the patients had had previous treatment, but in none of them had the disease been satisfactorily controlled. Two patients had had previous vulvectomies, one for carcinoma of the vulva and the other for leukoplakia of the vulva. Both of these had postoperative recurrence of leukoplakia with pruritus. Fifteen of the 25 patients had primary atrophy (kraurosis), 4 had leukoplakia, and 6 had primary atrophy with leukoplakia. Patients who presented a severe inflammatory reaction of the vulva with intense pruritus were initially treated with 0.1% fluorocortisone acetate ointment as a anti-inflammatory agent. Its use was discontinue as soon as the inflammatory reaction improved The patients were then instructed to apply to the vulva the testosterone propionate–oil preparation 10 cc. of which (50 mg. of testosterone propionat per cubic centimeter) was combined with 10 Gm of white petrolatum. Oral or parenteral therap with estrogen was not prescribed. No lesions wer excised except for biopsy; no surgery was done fo contracture of the introitus. Four patients had incision of a vaginal phimotic foreskin under loca anesthesia. All 25 patients were followed for sufficient period, varying from 3 months to 6½ years, to judge the efficacy of the treatment. On of the 25 patients has been lost to recent follow-up, but the remaining 24 are still under observation.

All 25 patients received satisfactory symptomatic relief of their pruritus and irritation within 1 to 6 weeks, accompanied by healing of abrasions and fissures. Grossly leukoplakic plaques regressed, although some required several months. All patients had a return of symptoms and progression of the disease within 1 to 6 months after omission of the testosterone ointment. Continued therapy thus has been required. None of the patients showed evidence of hirsutism, voice changes, or acne, even after prolonged therapy. All had some hypertrophy of the clitoris, which persisted and prevented the recurrence of phimosis. Depigmented areas of the vulvar skin were not observed to have a return of pigment. There has been no allergy due to the medication. Several of the patients developed an intertriginous dermatitis of the vulva during the early weeks of therapy. This disappeared under symptomatic treatment and did not recur with continued use of the testosterone ointment. Satisfactory relief of symptoms, without recourse to surgery, and apparent arrest of the disease process have been accomplished with this method of treatment.

The Possible Role of Smegma in Carcinoma of the Cervix. H. C. Heins Jr., E. J. Dennis and H. R. Pratt-Thomas. Am. J. Obst. & Gynec. 76:726-735 (Oct.) 1958 [St. Louis].

The authors performed experiments on mice into whose cervices and upper vaginas raw human smegma, obtained by retraction of the foreskin and evacuation of this material from about the glans in uncircumcised male inmates at the South Carolina State Hospital in Columbia, was applied repeatedly by 2 basic methods; these methods were by means of a metal speculum and by the injection of a single "dose" into the vagina followed by closure of the vaginal orifice with sutures. Biweekly vaginal injections of culture of 100% Mycrobacterium smegmatis and biweekly injections of 100% Myco. smegmatis in culture with 5% cholesterol also were performed on mice. Of 88 mice used for the injection of raw smegma followed by vaginal ligation, epidermoid carcinoma occurred in 8 (10%) and marked hyperplastic changes in 22 (25%). Thus, there were significant changes in 35% of the animals. These results show that carcinoma of the cervix can be produced by human smegma if the stimulus is continued for 14 months or more. Whole smegma, as well as some of its components, is stimulatory to the cervicovaginal epithelium of mice, and invasive carcinoma will eventuate if the stimulus exists. Whole raw smegma has proved to be the most effective stimulus in these experiments. The objections to the use of lower animals in reference to human cancer are obvious. A similar study with the use of an experimental animal of primate level is contemplated.

The Origin of Fetal Malformations: The Case of a Rare Monster. F. De Gennaro. Minerva ginec. 10:543-551 (July 31) 1958 (In Italian) [Turin, Italy].

A woman, 38 years of age, was delivered of a stillborn monster at the 7th month of pregnancy, after previously having had 3 normal children. The history of the parents revealed nothing unusual, except that the mother was underfed during pregnancy. The newborn infant had normal extremities, mouth, and ears but a short neck and no nape. A large eyeball with 2 pupils was set in a cavity in the middle of the upper third of the face. A small fleshy protrusion, 2.5 cm. (1 in.) in size, rose just above the eye cavity. Behind the protrusion, a large, dark, vesicular mass replaced the skull and extended over the posterior part of the neck. The ribs showed defective development and absence or fusion of parts. The skull had the frontal bone, but the ethmoid, vomer, inferior nasal conchae, lacrimals, and nasal bones were absent. The encephalon was not divided into hemispheres but consisted of a single vesicle.

Surgical and Radiologic Treatment of Cancer of the Cervix in 397 Cases. H. C. Frick II, J. A. Corscaden, H. W. Jacox and H. C. Taylor Jr. Surg. Gynec. & Obst. 107:457-468 (Oct.) 1958 [Chicago].

After 1944 radical surgery was reintroduced into the program for treatment of cancer of the cervix in the hope that its use in appropriate instances would increase the number of cures. This report is concerned with 397 patients who were admitted with a diagnosis of carcinoma of the cervix to 2 New York hospitals, the Sloane Hospital for Women, from 1944 to 1951 inclusive, and the Francis Delafield Hospital, for the single year, 1951. It follows previous reports of end-results in cancer of the cervix from the Columbia-Presbyterian Medical Center, the most recent prior publication being for the years 1939-1943. The 5-year end-results in 368 patients treated for cancer of the cervix during the years 1946-1951 are discussed. These included 118 patients with stage 1, 96 with stage 2, 70 with stage 3, and 19 with stage 4, as well as 32 patients with cancer of the cervical stump and 33 with recurrence of previously treated cancer.

In the 1946-1951 series, 232 patients were treated by radiation and 71 underwent surgery among the 303 patients with primary lesions of the cervix, exclusive of the cervical stump. The relative 5-year cure rate for all primary cases was 42.6%. [The relative 5-year cure rate for the 1939-1943 series, when all the patients were treated by radiation, was 43%.] The 5-year cure rate for stages 1 and 2, when surgery was the primary mode of therapy, was 86.5 and 42.1% respectively. Similar figures for those treated by intracavitary and interstitial radiation were 56 and 44.1% respectively. The 5-year cure rate for patients in stage 2 treated by interstitial implantation of radium was 50%. It was noted that there were somewhat earlier cases in the surgical series, somewhat fewer patients with severe constitutional disease, and a much smaller percentage in whom follow-up examination was incomplete.

The authors conclude that surgical treatment in stage 1 cases yielded a higher 5-year survival rate than did radiation therapy. Various factors, particularly of case selection, made the two series not wholly comparable and leave the question of the absolute superiority of one method of treatment over the other unanswered. The application of radical surgical methods of treatment to 76 (22%) of 335 cases of primary cervical cancer has been associated with a slight, but statistically not significant, improvement in the total cure rate.

The Incidence of Spontaneous Cure of Secondary Amenorrhea and Oligohypomenorrhea. A. Westman. Acta obst. et gynec. scandinav. 37:261-269 (No. 3) 1958 (In English) [Stockholm].

In order to investigate the incidence of spontaneous cure of secondary amenorrhea and oligomenorrhea, the author studied 2,262 pregnant women, their ages ranging from 19 to 40 years, who were admitted to the antenatal clinic of the Karolinska Sjukhuset in Stockholm during the year 1956-1957. About 60% of these patients had previously been pregnant. The fact that each patient was pregnant was proof-positive of normal ovarian function, i. e., that a previous disturbance, if it had been present, had been cured. Each patient was given a questionnaire in which she was requested to give information about her previous menstrual history. In 173 (7.7%) of these patients there was a history of amenorrhea and/or oligomenorrhea. Of the 173 patients, 85 gave information about the possible causative factors; it appeared that environmental conditions, place of residence or working conditions, and nervous troubles played an important part in those patients in whom the menstrual disturbance had been of short duration. Most of the menstrual disturbances of more than 12 months' duration had come on after childbirth. A critical analysis of these cases has suggested that spontaneous cure occurs in about 80% of the cases, including those in which the duration of the menstrual disturbance has been up to 3 years. According to the literature, hormone therapy is effective in 50% of the cases. However, the value of this treatment appears to have been overestimated; the true percentage of cases in which it results in cure probably is 20%.

Maternal Death Due to Pulmonary Embolism by Amniotic Fluid. F. A. Carone and J.-G. Regueiro Castro. West Virginia M. J. 54:384-390 (Oct.) 1958 [Charleston].

The case reported is that of a 41-year-old woman, gravida 2, para 1, who was admitted on Jan. 10 at 1:30 p. m., the estimated date of confinement being Jan. 9. When first examined, the patient was thought to be in early labor, with irregular contractions. The fetal head was approximately 2 cm. above the ischial spines, and the cervix was 2 cm. dilated. During the first hour after admission, the labor progressed rapidly and by 3:15 p. m. the cervix was 6 cm. dilated. Demerol was given to ease pain. At 3:30 p. m the patient began to cough and to gasp for air. Within a few seconds she experienced extreme air hunger, stopped breathing, and had a convulsive episode. The blood pressure and pulse were not obtainable. An airway was established, and oxygen was administered. Tracheotomy was begun, but when it became obvious that death had occurred, the operation was not completed. The baby was delivered vaginally with forceps approximately 15 minutes after the mother's death, and, after the usual resuscitative measures, its respiration became established.

On autopsy, significant microscopic lesions were found in the heart, lungs, and uterus of the mother. Foreign material, consisting of squamous cells, mucin, bile pigment, and fat, was found in the pulmonary vessels. Squamous cells, hair, and strands of mucin with clusters of leukocytes were demonstrated in both smears and cell-block preparations of blood from the right heart. The concentration of amniotic particulate matter in right heart blood may have been greater in this case since death occurred in less than 5 minutes, presumably due to massive embolism. Since the particulate constitutents of amniotic fluid have a lower specific gravity then the cellular elements of blood, they settle out as a flocculent layer above the leukocytic cream. Thus, the presence of 3 strata instead of 2 in centrifuged blood from the right heart should be considered pathognomonic for this condition. This procedure may be utilized to establish the diagnosis of amniotic fluid embolism in cases lacking autopsy permission. It is probable that many maternal deaths, without autopsies and labeled thrombotic pulmonary embolism, obstetric shock, or postpartum hemorrhage, actually are fatalities due to amniotic fluid embolism. Some of the deaths which have resulted from amniotic fluid embolism could have been prevented if the proper measures had been instituted. Embolization of the lungs should be considered likely if unexplained cyanosis and shock develop during labor, and oxygen should be administered at once. Papaverine hydrochloride may be given to abolish reflex vascular spasm of the pulmonary vessels and thus prevent pulmonary edema, and atropine or atropine-like agents may be given to abolish cardiac depressor reflexes from the lungs.

When pulmonary edema develops, it should be treated vigorously, and withdrawal of blood may be indicated. Unfortunately, the two measures commonly used to combat shock, i. e., blood transfusion and administration of epinephrine-like compounds, worsen pulmonary edema. Clinical judgment is important in using these agents in patients with amniotic fluid embolism. If death does not occur, attention should be directed to the possible onset of hemorrhagic tendencies because of coagulation defects secondary to infusion of amniotic fluid constituents into the maternal circulation. Incoagulibility of the blood may result and intravascular coagulation may produce hypofibrinogenemia. If this condition exists, it should be corrected by administration of adequate amounts of fibrinogen.

Kyphoscoliosis and Pregnancy. R. Marchand. Laval méd. 26:309-315 (Oct.) 1958 (In French) [Quebec].

Pregnancy in patients with extensive malformation of the vertebral column usually leads to complications of an unsuspected gravity. Few obstetricians know the danger of cardiopulmonary failure in pregnant women with kyphoscoliosis. The influence of deviations of the spinal column varies greatly according to the seat, form, size, and age at onset of the condition. This study is of patients in whom kyphosis or extensive kyphoscoliosis appeared at an early age. This disease produces a marked vertical compression of the thoracic cage with considerable diminution of the respiratory capacity. The resulting interference with pulmonary circulation brings on hypertrophy of the right heart and later lesions of the myocardium. These patients, who are poor risks for general anesthesia and major surgery, tolerate pregnancy with difficulty. The increase in the volume of the abdomen adds to the intrathoracic compression and restrains the respiratory capacity, which is already diminished by the rigidity of the rib cage. The heart must use more strength to overcome this new resistance and circulatory overloading. Delivery requires a physical effort which may be fatal, especially considering the fact that kyphoscoliosis is frequently accompanied by abnormalities of the pelvis. These may make natural delivery impossible, and it is often necessary to terminate the pregnancy by cesarean section.

The author discusses the cases of 3 patients. The first, a primipara aged 30 years, had pronounced thoracic kyphoscoliosis which had begun at the age of 11. On admission to the hospital, she had incipient toxemia of pregnancy, edema of the legs, albuminuria of 3 Gm., and a light hypertension of 140/90. The pelvis seemed a little asymetrical and the external diameters slightly diminished, but the upper passage seemed permeable. Labor was artificially induced 2 weeks before term, and natural delivery was seen to be impossible. Five days later a healthy baby was delivered by classic cesarean section. Six days after delivery the patient died of asystole and infection of the right lung. In the second case a woman, aged 38 years, who had had kyphoscoliosis since the age of 4, died of cardiopulmonary failure 13 days after a cesarean section; until then the condition had had no serious consequences. In the third case a woman of 34, with pronounced kyphoscoliosis of the thoracic spine, dyspnea, and rales but whose myocardium was apparently healthy, was treated with digoxin 5 days before surgery. The fetus was premature and cyanosed and died 24 hours after delivery; autopsy revealed pulmonary atelectasis and a hyaline membrane. The mother, who continued to receive cardiac medication several days after delivery, suffered no severe postoperative symptoms.

Pregnant kyphoscoliotic patients should not be treated with medicines and interventions capable of interfering with pulmonary ventilation and the circulation of the blood. The coexistence of a large deformation of the thoracic spine with pregnancy constitutes an immediate danger for the mother and child and poses a difficult problem for the obstetrician, as shown by the deaths of two of these mothers and one of the babies.

Cystadenocarcinoma of the Ovary and Uterine Pregnancy. C. Chávez and P. Chávez. Arch. peruanos pat. y clín. 12:191-195 (June) 1958 (In Spanish) [Lima, Peru].

Uterine pregnancy which is complicated by either benign or malignant cystadenoma of the ovaries occurs with moderate frequency. According to the literature, the tumor does not interfere with pregnancy, nor does it damage the fetus. Yet the death rate among fetuses in pregnancies associated with ovarian tumors is high (18%). A tripara woman at full term was hospitalized with an enormous abdomen from ascites and with edema from the abdomen to the ankles. A plain roentgenogram of the abdomen confirmed the presence of the fetal skeleton. A diagnosis of polyhydramnios with a living fetus was made. Four days after hospitalization the woman gave birth spontaneously to an infant who was cyanotic and died a few hours after birth. Autopsy showed marked dilatation of the cerebral ventricles, which seemed to have been the cause of death. The mother developed pleurisy during the puerperium, which was controlled by the administration of antibiotics. Two abdominal paracenteses, by which 5,000 and 7,000 cc., respectively, of ascitic fluid were drawn off, were made 2 weeks after parturition. An enormous ovarian tumor was palpated after the paracenteses. The operation consisted of bilateral oophorectomy and removal of the tumor, which was fixed by adhesions to the anterior wall of the abdomen and by a large base to the posterior wall. There were no metastases, but histological study of the tumor showed it to be a cystadenocarcinoma. The postoperative period was uneventful. The patient was given blood transfusions and antibiotics and one week later, after edema had disappeared, was discharged from the hospital. Examination 3 years after the operation has shown that her condition is satisfactory.

Pre-Natal Fetal Electrocardiography. P. Bergman and P. Hall. Acta obst. et gynec. scandinav. 37:348-357 (No. 3) 1958 (In English) [Stockholm].

The authors report a study on 449 prenatal fetal electrocardiograms obtained from 368 patients in the department of obstetrics and gynecology of the general hospital in Malmö, Sweden. Of the 449 electrocardiograms, 277 (obtained from 239 patients whose pregnancy terminated in normal delivery or legal abortion) were taken during the 15th week of pregnancy or later. Detailed data concerning these 277 electrocardiograms showed that prenatal fetal electrocardiography was useful in investigating obstetric cases in which no fetal heart sounds could be heard and in which there was reason to suspect fetal death. In 6 of 28 such patients the electrocardiogram was positive, i. e., it showed measurable, or immeasurable but nevertheless distinct, potentials in 5 consecutive fetal complexes and therefore objective signs of a living fetus; 4 of these women were later delivered of living infants. The first electrocardiograms obtained from the remaining 2 patients gave a positive result, which was subsequently verified when normal fetal sounds were heard. Electrocardiograms taken on later occasions, however, contained no fetal complexes, and the fetuses which were subsequently delivered of these patients were macerated. Since the electrocardiogram was not always positive even when the fetus was alive, a negative record might be less informative.

Prenatal fetal electrocardiography is also a useful guide in the evaluation of the position of the fetus, but with the technique applied in the present investigation the method proved less satisfactory in the diagnosis of twin pregnancies. The amplitude of the QRS complex increases during the last 2 months of pregnancy to reach a maximum at term. If pregnancy proceeds beyond the calculated term, this complex seems to decrease in amplitude. It, therefore, appears that prenatal fetal electrocardiography might be useful in the detection of true postmaturity if serial examinations are made.

PEDIATRICS

Bacterial Endocarditis in Children with Heart Disease. J. G. Cutler, P. A. Ongley, H. Shwachman and others. *Pediatrics* 22:706-714 (Oct., Part 1) 1958 [Springfield, Ill.].

The authors report on 12 boys and 12 girls, between the ages of 8 months and 16 years, with bacterial endocarditis and with preexisting congenital or rheumatic heart disease, who were admitted to the Children's Hospital and the House of the Good Samaritan in Boston between 1944 and 1956. In the group of 6 patients with congenital heart disease of cyanotic type, bacterial endocarditis occurred most commonly in those with tetralogy of Fallot, since 5 of the 6 patients had this congenital defect. In the group of 9 patients with congenital heart disease of acyanotic type, there was a slight predominance of those with ventricular septal defect and coarctation of the aorta. In the group of 9 patients with rheumatic heart disease, mitral insufficiency was the predominant lesion.

The duration of symptoms attributable to bacterial endocarditis before admission to hospital varied from 5 days to 9 months. Twenty-two of the 24 patients were admitted with a history of fever, which subsided when therapy was instituted. Anorexia with associated weight loss was present in 20 patients. Joint pains occurred in 9 patients, and clubbing in 10. Murmurs were noted in all patients. Twenty patients had cardiac hypertrophy, which was progressive since the onset of endocarditis in 10 patients with congestive heart failure. In 12 patients embolism occurred, most frequently in the lungs or brain. Petechiae were observed in 12 patients. Enlargement of the liver was present in 8 patients, and enlargement of the spleen in 16. There was poor dental hygiene with multiple caries in 11 patients. The causative relationship between this physical finding and bacterial endocarditis warrants repeated emphasis. A significant anemia of either normochromic or hypochromic type was present in 19 patients.

Alpha-hemolytic streptococci were isolated from 13 patients, including 7 of the 15 with congenital heart disease and 6 of the 8 with rheumatic heart disease. Three of these 13 patients died. In 2 patients, 1 of whom died, Staphylococcus pyogenes var. aureus was the offending agent. Pneumococci, beta and gamma streptococci, hemophilus parainfluenzae, and Pseudomonas organisms were detected in the remaining patients. Twenty patients (83%) recovered from the acute illness. Antibiotics were used in 23 of the 24 patients. Aqueous salts of penicillin were considered to be the drugs of choice in the treatment of all streptococcic infections. Because of the gravity of the infection, a minimum duration of 3½ weeks of treatment was adhered to. The parenteral route of administration seemed to assure more predictable and uniform concentrations of penicillin in the blood than the oral route. The measure of in vitro sensitivity of the offending organism was used as a guide in the selection of antibiotic agents in nonstreptococcic infections. The prognosis depends on the interval between the onset of illness and the institution of therapy, the sensitivity of the infecting organism to the antibiotics used, adequate dosage of the antibiotics, the severity of the underlying heart disease, and the development of complicating factors, such as congestive heart failure or embolism in vital organs, which are bad prognostic signs despite effective antibiotic therapy.

Salmonellosis in a Premature Nursery Unaccompanied by Diarrheal Disease. J. Watt, M. E. Wegman, O. W. Brown and others. *Pediatrics* 22:689-705 (Oct., Part 1) 1958 [Springfield, Ill.].

The authors report on an epidemic of salmonellosis which occurred in the premature unit of the Charity Hospital of Louisiana in New Orleans. The introduction into this large nursery of 6 apparently healthy premature infants, who were later found to be infected with Salmonella tennessee, led to an epidemic spread of the infection over a 4-month period. None of the 6 infants whose initial rectal swabs yielded Sal. tennessee, a potential pathogen, and none of the 28 additional infants whose cultures became positive after initial spread of the Salmonella infection in this nursery had taken place were clinically ill at any time. Of 130 positive Salmonella cultures which were obtained from the 34 infants, 104 (80%) were found to be positive without the aid of enrichment technique. Six of the 34 infants known to have been excreting Sal. tennessee would have escaped detection if enrichment mediums had not been used.

The original source of the infection could not be determined. Feedings, contact with other patients, and infected animals could be eliminated as modes of spread. Rectal-swab cultures of nurses and attendants were all negative. Infection of air was revealed by obtaining Sal. tennessee from one of 30 swab samples taken of air-conditioning filters. Positive Salmonella cultures were obtained from bedside tables and recently changed cribs. A positive culture was obtained from the hands of one nurse immediately after washing. Evidence was found that increase in the spread of the infection was associated with decrease in amount of nursing care. It is inferred that defective nursing techniques, particularly hand washing, were the chief mode of spread. This outbreak was unique in that an identifiable member of a frequently pathogenic group caused infection but not illness. In similar outbreaks, thorough hand washing should be emphasized as an important and efficient barrier between infected and noninfected infants.

Contribution to the Study of the Incidence of Morbidity and of Disorders Secondary to Serofibrinous Pleurisy in the Course of Pulmonary Tuberculosis in Children in the Period Before and After the Advent of Antibiotics. F. Batini and F. Biondi. Gior. clin. med. 39:1123-1143 (July) 1958 (In Italian) [Bologna, Italy].

The authors review the incidence of morbidity and of disorders secondary to serofibrinous pleurisy among 7,312 hospitalized children, aged 2 to 15 years, with pulmonary tuberculosis in the period before (1933-1948) and after the advent of antibiotics and other anti-infectives (1949-1956). Serofibrinous pleurisy developed in 292 children, one-half of whom had the disease on admission; in the other half it developed during the hospitalization period. The incidence of serofibrinous pleurisy was higher among boys (157) than among girls (135). The patients were followed up for 9 months after the remission of serofibrinous pleurisy for possible development of disorders secondary to this disease.

During the period preceding the use of anti-infectives (1933-1948), 207 children had serofibrinous pleurisy, and 174 (84%) recovered. The condition of 7 patients remained unchanged, and that of 19 deteriorated; 7 patients died. Disorders secondary to serofibrinous pleurisy developed in 73 children. During the period (1949-1953) when streptomycin and aminosalicylic acid were used in treating 62 patients with serofibrinous pleurisy, 59 (95.2%) were cured, but the condition of 3 became worse. Disorders secondary to serofibrinous pleurisy developed in 5 patients. During the period (1954-1956) when isoniazid was used in treating 23 patients with serofibrinous pleurisy, all the patients were cured, and disorders secondary to this disease developed in only 1.

The incidence of serofibrinous pleurisy as a complication which developed during the hospitalization of children with pulmonary tuberculosis decreased considerably on the advent of antibiotics and, in particular, after the introduction of the antibacterial agent, isoniazid. However, the occurrence of this form of pleurisy as an accompaniment to tuberculous disease on admission in this group of children remained unchanged in terms of percentage, but the age at incidence was raised, on an average, from 11 to 15 years. The authors suggest prolonged maintenance therapy with anti-infectives in children who have recovered from serofibrinous pleurisy as a form of chemotherapeutic prophylaxis for the prevention of disorders secondary to this disease.

Acute Poisoning Associated with Inhalation of Mercury Vapor: Report of Four Cases. F. T. Matthes, R. Kirschner, M. D. Yow and J. C. Brennan. Pediatrics 22:675-688 (Oct., Part 1) 1958 [Springfield, Ill.].

The authors report on 4 members of a Negro family, a 19-year-old mother and 3 children, aged 30, 20, and 4 months, respectively, who were brought to Jefferson Davis Hospital in Houston, Texas, about 36 hours after exposure to mercury vapor. The mother had painted a small gas space-heater with a mixture of mercury, turpentine, and aluminum paint and had heated the stove in an attempt to make the mixture adhere to the surface. The heater was allowed to burn all night while the mother and children were asleep in their 2-room home. The 20-month-old infant was dead on admission to hospital, and the other 2 infants died 66 hours and 5 days, respectively, after the onset of symptoms. The mother was acutely ill for 48 hours after her admission, and thereafter there was steady improvement. The illness of all 4 patients was characterized by the sudden onset of tachypnea, cough, fever, gastrointestinal disturbances, and central nervous system manifestations. Ordinary laboratory tests were not helpful in establishing the diagnosis. Quantitative analysis of the urine for mercury was suggestive but not diagnostic. Chest roentgenograms revealed interstitial pneumonitis. Autopsies were performed on the 3 children, and analysis of tissue for mercury in the lungs, liver, and spleen of 2 showed substantially increased mercury content. The outstanding pathological features in the 3 children were erosive bronchitis and bronchiolitis, with severe interstitial pneumonitis.

At the present time the most generally accepted therapy for acute poisoning caused by ingestion of mercury consists of early administration of dimercaprol (BAL). Its use is probably also indicated in acute poisoning caused by inhalation of mercury vapor. Supportive care in the form of oxygen, mist, and parenterally administered fluids is indicated.

The Treatment of Acute Respiratory Infection in Infants. H. I. A. Nisbet and F. Wilson. Brit. J. Anaesth. 30:419-434 (Sept.) 1958 [Altrincham, England].

In spite of modern advances in treatment, there is still a significant rate of mortality among infants who suffer from acute respiratory infections. Failure to clear secretions from the air passages results in severe respiratory obstruction and increasing hypoxia. Oxygen demand is increased by virtue

Ninety patients, in whom severe pruritus was a distressing and complicating factor in acute and chronic dermatoses and systemic diseases, were treated with trimeprazine in the course of the past year. The patients selected were chiefly those in whom pruritus had been completely or partially refractory to other forms of therapy, such as topical applications or systemic administrations of steroids, antihistamines, sedatives, and tranquilizers. They ranged in age from 1 year to 75 years; 68 were female, and 22 were male. All but 2 were ambulatory. The initial dose consisted of one 2.5-mg. tablet taken 2 or 3 times a day. As the study progressed, it was evident that drowsiness, a mild side-effect, could be largely eliminated by having the patients take their dose of trimeprazine just prior to meals. The dose taken before retiring was usually twice the daytime dose because of increased nighttime itching. Even though nighttime doses were sometimes as high as 20 mg., lethargic effects the following morning were reported by only one patient. The author concludes that trimeprazine is an effective antipruritic when given orally and that it can be administered in small daily doses. It produces no serious untoward effects, even upon prolonged administration, and permits a reduction in concomitant therapy.

The Nylon Brush. A. Savill. Brit. J. Dermat. 70:296-299 (Aug.-Sept.) 1958 [London].

The author comments on the histories of several patients who complained of hairfall which ceased when a nylon brush was replaced by a bristle brush. Several persons on being questioned admitted that, when brushing with a nylon brush, more hair came out than when brushing with a bristle brush. In the use of nylon brushes some hairs appear to be pulled out with roots intact. The old-fashioned hair brush is becoming rare, since its bristles, taken from hogs and wild boars of Siberia and the coldest regions of Manchuria, are now difficult to obtain. The need to produce another type of brush resulted in the nylon brush. The bristles of this brush are composed of monofilaments of synthetic nylon, which are cut to the required length; this process can leave an uneven square end, which is injurious.

In studying various types of nylon brushes under a magnifying glass, the author found that nylon bristles have different types of points: (1) rounded points, like the head of a match—safe to use; (2) square points, which look as if cut square—not safe; and (3) square-cut ends, gently rounded off—not so harmful. Furthermore, some firms are replacing nylon bristles with molded Polythene quills which are smooth and resilient, with rounded ends. This kind of brush ensures that the hair shafts do not become entangled, frayed, or pulled out by the roots.

UROLOGY

Treatment of Carcinoma of the Bladder. J. C. Anderson. Brit. J. Urol. 30:330-337 (Sept.) 1958 [Edinburgh].

Although bimanual pelvic examination may help by proving or excluding the presence of gross invasion of the pelvic cellular tissues, or microscopic examination of fragments obtained by various means may yield some information regarding the character or activity of the tumor, the cystoscopic appearance is the most certain guide to treatment of bladder carcinoma, and it is of paramount importance that the surgeon and radiotherapist should cooperate. The author seldom uses general anesthesia for cystoscopy but generally only a local anesthetic. For the induction of deeper anesthesia he uses a caudal or sacral, but never a spinal, anesthetic. Some information is gained as the cystoscope is passed; it may impinge on a growth or be deflected. The patient empties his bladder before he comes for examination, and residual urine is noted. The ease with which the bladder is washed clear and its capacity are informative. The cystoscopic appearance of the tumor determines the choice of treatment, although the age and physical condition of the patient and the infection may influence it to some extent.

The choice is governed by the desire to keep the ureters in the bladder as long as possible. If the villi are fine and the base narrow, with no surrounding epithelial change, varicosity, or sign of lymphatic obstruction, cystoscopic diathermy is employed, even if the lesions are multiple. Suction or transurethral resection may help to reduce the size of a large tumor. If the lesions are recurrent or multiple, the posterior part of the urethra is examined for seedlings. If the tumor is too large for accurate assessment, open operation may be advisable. The author decides upon an open operation (1) when the tumor has blunted fronts, has a wider base, is sessile, or if there are varicosities or a velvety creep from the base; also when there are satellites close to it or other local or diffuse epithelial changes and (2) if the tumor is solid, nodular, or invasive, is less than 3 or 4 cm. in diameter on the base of the bladder or 5 cm. in diameter elsewhere, and has not invaded the pelvic cellular tissues. Bullae appear when the growth invades the bladder wall: the bullous edema is gross, and the bladder becomes fixed when the growth invades the pelvic cellular tissues.

If the diameter of the growth is more than 4 cm. and it has invaded the extravesical tissues, then supervoltage roentgen-ray irradiation is the treatment of choice. Multiple papillomas should be kept under control by cystoscopic diathermy for as long as possible. When this is impossible, a choice must be made between wide partial cystectomy, supervoltage roentgen-ray irradiation, or, when these of the increased respiratory effort, while oxygen supply is diminished because of the defective ventilation. When such a state of respiratory insufficiency exists, antibiotics are of little value unless the airway can be maintained until such time as they can exert their beneficial effect. Similarly, an obstructed airway must reduce the value of oxygen therapy. Methods by which this state of respiratory insufficiency may be alleviated are discussed. These include the use of endotracheal intubation, suction, bronchoscopy, tracheotomy, posture, and humidity; and of controlled respiration in cases in which the infant is too weak to maintain adequate ventilation by its own unaided efforts.

A series of 18 infants treated by such methods is described. Thirteen of these infants survived. Several case histories are presented in some detail, while the others are included in tabular form. The 5 deaths are discussed. In certain of these cases the presence of associated lesions rendered survival unlikely. Some complications are mentioned, in particular those arising from endotracheal intubation in infants. While these problems exist, they should not be held to contraindicate this procedure, especially in cases in which intubation and suction are essential for relief of respiratory obstruction and the reestablishment of adequate ventilation.

Sigmamycin in Pediatrics. J. Felder. Schweiz. med. Wchnschr. 88:953-958 (Sept. 27) 1958 (In German) [Basel, Switzerland].

Signemycin (Sigmamycin) is a combination of 2 parts of tetracycline and 1 part of oleandomycin. This combination drug was available for oral application in the form of capsules and of a sirup, and for intravenous and local application in the form of ampuls. The author reviews his experiences with it during a 6 months' treatment of 128 children, in 110 of whom the therapeutic result could be verified by clinical and bacteriological data. This group included children with septicemia, purulent meningitis, infections of the respiratory tract, osteomyelitis, arthritis, enteritis, infections of the urinary tract, purulent skin diseases, and suppurative lymphadenitis. A table shows that signemycin produced cure in 115 of the 128 children and failed in only 6. The therapeutic effect appeared promptly, and the drug was well tolerated. Secondary effects of the drug were observed in about one-fifth of the patients, but they were harmless, requiring premature interruption of the treatment in only one patient.

All strains of staphylococci that were tested were sensitive to signemycin. The reliable and prompt action of the drug and the fact that it can be administered by various routes and that it is well tolerated make signemycin one of the most useful therapeutic agents against serious bacterial infections caused by many different micro-organisms. In very acute cases, especially in septicemia, purulent meningitis, arthritis, osteomyelitis, and complicated pneumonia, the author recommends a high initial dosage, orally of 100 to 200 mg. per kilogram of body weight daily, or intravenously of 50 mg. per kilogram daily.

DERMATOLOGY

Effect of Oral Steroid on Non-Inflammatory Scalp Ringworm. N. M. Kanof. J. Invest. Dermat. 31:139 (Sept.) 1958 [Baltimore].

A 9-year-old Negro boy was seen at Children's Hospital, Washington, D. C., for alopecia areata of 2 years' duration. The child also had noninflammatory ringworm infection of the scalp with typical fluorescence of broken-off hairs on examination with Wood's light. After 2 weeks of oral therapy with prednisone (Meticorten), 5 mg. 4 times daily, for alopecia areata and of local therapy with diamthazol (Asterol) dihydrochloride ointment for the ringworm, there was a definite lessening of the number of fluorescent hairs in the ringworm sites. The application of Asterol ointment was then discontinued, and the patient was given only steroid therapy orally. At the end of 6 weeks there was no evidence of fluorescence under the Wood light. The alopecia areata was greatly improved.

Subsequently, a small pilot experiment was carried out on 8 children with noninflammatory tinea capitis due to Microsporum canis. All these patients had involvement of at least two-thirds of the scalp and had been refractory to topical therapy. After 4 to 10 weeks of oral therapy with prednisone, 20-25 mg. daily, all the patients demonstrated a marked change in the affected scalp hairs—either in a marked decrease in the number of broken-off fluorescent hairs or in a peculiar change of the fluorescence from brilliant emerald green to a grayish-white hue. It was especially interesting to note that, wherever fluorescence could no longer be observed, hairs of normal length were present. Further observations are required to confirm and to interpret these effects.

A New Oral Antipruritic. P. L. Williams. Northwest Med. 57:1162-1164 (Sept.) 1958 [Seattle].

This report is concerned with trimeprazine (Temaril), which is the tartrate salt of *dl*-10-(3-dimethylamino-2-methylpropyl)-phenothiazine. Since preliminary investigations with trimeprazine had indicated that this drug, when taken orally, exerts a potent and seemingly specific antipruritic effect in such unrelated conditions as biliary cirrhosis, poison ivy, and neurodermatitis, it seemed worthwhile to undertake an evaluation of trimeprazine in a private dermatological practice to elucidate its antipruritic effect.

Ninety patients, in whom severe pruritus was a distressing and complicating factor in acute and chronic dermatoses and systemic diseases, were treated with trimeprazine in the course of the past year. The patients selected were chiefly those in whom pruritus had been completely or partially refractory to other forms of therapy, such as topical applications or systemic administrations of steroids, antihistamines, sedatives, and tranquilizers. They ranged in age from 1 year to 75 years; 68 were female, and 22 were male. All but 2 were ambulatory. The initial dose consisted of one 2.5-mg. tablet taken 2 or 3 times a day. As the study progressed, it was evident that drowsiness, a mild side-effect, could be largely eliminated by having the patients take their dose of trimeprazine just prior to meals. The dose taken before retiring was usually twice the daytime dose because of increased nighttime itching. Even though nighttime doses were sometimes as high as 20 mg., lethargic effects the following morning were reported by only one patient. The author concludes that trimeprazine is an effective antipruritic when given orally and that it can be administered in small daily doses. It produces no serious untoward effects, even upon prolonged administration, and permits a reduction in concomitant therapy.

The Nylon Brush. A. Savill. Brit. J. Dermat. 70:296-299 (Aug.-Sept.) 1958 [London].

The author comments on the histories of several patients who complained of hairfall which ceased when a nylon brush was replaced by a bristle brush. Several persons on being questioned admitted that, when brushing with a nylon brush, more hair came out than when brushing with a bristle brush. In the use of nylon brushes some hairs appear to be pulled out with roots intact. The old-fashioned hair brush is becoming rare, since its bristles, taken from hogs and wild boars of Siberia and the coldest regions of Manchuria, are now difficult to obtain. The need to produce another type of brush resulted in the nylon brush. The bristles of this brush are composed of monofilaments of synthetic nylon, which are cut to the required length; this process can leave an uneven square end, which is injurious.

In studying various types of nylon brushes under a magnifying glass, the author found that nylon bristles have different types of points: (1) rounded points, like the head of a match—safe to use; (2) square points, which look as if cut square—not safe; and (3) square-cut ends, gently rounded off—not so harmful. Furthermore, some firms are replacing nylon bristles with molded Polythene quills which are smooth and resilient, with rounded ends. This kind of brush ensures that the hair shafts do not become entangled, frayed, or pulled out by the roots.

UROLOGY

Treatment of Carcinoma of the Bladder. J. C. Anderson. Brit. J. Urol. 30:330-337 (Sept.) 1958 [Edinburgh].

Although bimanual pelvic examination may help by proving or excluding the presence of gross invasion of the pelvic cellular tissues, or microscopic examination of fragments obtained by various means may yield some information regarding the character or activity of the tumor, the cystoscopic appearance is the most certain guide to treatment of bladder carcinoma, and it is of paramount importance that the surgeon and radiotherapist should cooperate. The author seldom uses general anesthesia for cystoscopy but generally only a local anesthetic. For the induction of deeper anesthesia he uses a caudal or sacral, but never a spinal, anesthetic. Some information is gained as the cystoscope is passed; it may impinge on a growth or be deflected. The patient empties his bladder before he comes for examination, and residual urine is noted. The ease with which the bladder is washed clear and its capacity are informative. The cystoscopic appearance of the tumor determines the choice of treatment, although the age and physical condition of the patient and the infection may influence it to some extent.

The choice is governed by the desire to keep the ureters in the bladder as long as possible. If the villi are fine and the base narrow, with no surrounding epithelial change, varicosity, or sign of lymphatic obstruction, cystoscopic diathermy is employed, even if the lesions are multiple. Suction or transurethral resection may help to reduce the size of a large tumor. If the lesions are recurrent or *multiple*, the posterior part of the urethra is examined for seedlings. If the tumor is too large for accurate assessment, open operation may be advisable. The author decides upon an open operation (1) when the tumor has blunted fronts, has a wider base, is sessile, or if there are varicosities or a velvety creep from the base; also when there are satellites close to it or other local or diffuse epithelial changes and (2) if the tumor is solid, nodular, or invasive, is less than 3 or 4 cm. in diameter on the base of the bladder or 5 cm. in diameter elsewhere, and has not invaded the pelvic cellular tissues. Bullae appear when the growth invades the bladder wall: the bullous edema is gross, and the bladder becomes fixed when the growth invades the pelvic cellular tissues.

If the diameter of the growth is more than 4 cm. and it has invaded the extravesical tissues, then supervoltage roentgen-ray irradiation is the treatment of choice. Multiple papillomas should be kept under control by cystoscopic diathermy for as long as possible. When this is impossible, a choice must be made between wide partial cystectomy, supervoltage roentgen-ray irradiation, or, when these have failed, total cystectomy, always remembering that the posterior part of the urethra may be involved as well as the bladder. After cystectomy it is better to create an ileal bladder, because the ureters are divided and anastomosed at a higher level where their blood supply is better. One type of bladder carcinoma difficult to diagnose resembles eczema and is accompanied by intense dysuria. The appearance is explained by rapid intramural spread. The prognosis is bad unless supervoltage roentgen-ray irradiation is given early. A dose of 5,000 or 6,000 r is aimed at. The results of treatment by supervoltage irradiation are miraculous, particularly in the solid infiltrating carcinoma which may vanish, leaving an apparently healthy mucosa. If it does not disappear completely, it may shrink; if ulcerated, it may heal; and, as a rule, it stops bleeding. The patient may be free from pain and discomfort for several years, perhaps until he dies of some other condition. After a lapse of time the growth may come to life again, but cystectomy or ureteric transplant can still be done.

The Investigation and Significance of Persistent and Recurrent Urinary Infection in Children. W. I. Forsythe and I. R. Wallace. Brit. J. Urol. 30:297-302 (Sept.) 1958 [Edinburgh].

In children with persistent or recurrent urinary infection, it is important to use all available diagnostic procedures in order to discover the true nature of the malady before irreparable damage is done to the urinary system. The authors present observations on 17 boys and 34 girls who were investigated because of persistent and recurrent urinary infection. Except for 3 boys who were 18 months (2) and 2 years old, respectively, the ages of the 51 children ranged from 4 to 14 years. Eight boys and 11 girls had persistent urinary infection, and 9 boys and 23 girls had recurrent urinary infection. Of the 19 children with persistent infection, 5 boys and 6 girls showed abnormalities. Of the 32 children with recurrent infection, 9 boys and 13 girls showed abnormalities. A critical analysis of the symptoms did not show any significant difference between the patients with abnormalities and those without. The clinical examination was of little value because, apart from 2 children with palpable bladders, no abnormal physical signs relevant to the genitourinary tract were found. In 20 children the infecting organism was Escherichia coli, and in the remainder a variety of organisms was found. Intravenous pyelography revealed abnormalities in 18 cases, but the true nature of these was not appreciated in 9 cases until micturition cystography was undertaken, and in 4 cases retrograde pyelography was needed before the exact nature of the abnormality was discovered. Micturition cystograms revealed abnormalities in 26 cases, but the full nature of these was not appreciated in 9 cases until intravenous pyelography was undertaken, and in 2 cases retrograde pyelography was needed before the exact nature of the abnormality was discovered. Thus, in 28 cases intravenous pyelography and micturition cystography were sufficient to establish the complete diagnosis, and in only 5 cases was retrograde pyelography required.

The authors advise excretory urography and micturition cystography in the initial investigation of these children. If this procedure is followed, many children will avoid unnecessary instrumentation. Should the findings prove inconclusive, though, urethroscopy, cystoscopy, and retrograde pyelography must be undertaken. Observations on boys revealed that 67% of those with recurrent and 63% of those with persistent urinary infections had lesions causing obstruction or stasis. Of 19 girls with anomalies, only 1 showed an obstructive lesion; however, abnormal widening of the internal vesical sphincter and vesicoureteral reflux were common in girls. The cause of widening of the internal sphincter is unknown, but an infective origin is unlikely, because the authors found a similar anomaly in 26 girls with enuresis who had sterile urines and no history of urinary infection. A neurogenic cause cannot be excluded, because in many cases it is impossible to distinguish roentgenologically between the inverted spinning-top appearance of the wide bladder neck and the funneling of the vesical outlet in the neurogenic bladder. The authors think that the condition is due to hypotonia of the internal vesical sphincter, but they are unable to say whether or not it is congenital in origin. According to Hinman, urethral ascension to the bladder is a common cause of urinary infection in female infants and girls. An ascending infection is more likely to occur when the internal vesical sphincter is incompetent.

Hunner's Ulcer. C. H. Kinder and R. D. Smith. Brit. J. Urol. 30:338-343 (Sept.) 1958 [Edinburgh].

The authors review the records of cases classified as Hunner's ulcer at St. Peter's and St. Paul's hospitals in London during the last 10 years. In only 27 of the 42 patients classified as having this condition could Hunner's ulcer be definitely identified. The youngest patient was 33 years old and the oldest 71. No predisposing factor was found, but in 8 women symptoms apparently began after a pelvic operation or childbirth. It is possible that some of these pelvic operations were wrongly performed for symptoms produced by an undiagnosed Hunner's ulcer. There were only 2 male patients, aged 46 and 54 years respectively. The dominant symptoms of Hunner's ulcer were gross frequency, urgency, and pain. The most severely affected patients were confined to their homes because of frequency of micturition occurring as often as every quarter of an hour by day and up to 10 times by night. Pain was both suprapubic and urethral and in some instances was referred to the loin. It was made worse by a full bladder and relieved by micturition.

Physical examination was not helpful. The urine was usually clear apart from occasional hematuria, and any infection was incidental and inconstant. Most patients had had urograms done, and these were always normal apart from showing a contracted bladder in the worst cases. The bladder capacity was often reduced to 4 to 6 oz., rarely as low as 2 oz. Cystoscopy in the conscious patient was painful and the appearances variable. Small hemorrhagic patches were noted in the vault and lateral or posterior walls, which on close inspection often surrounded shallow irregular linear ulcers or trabecular scars. The rest of the bladder was smooth, pale, and parchment-like. The affected areas would heal, only to break down at a later date. The trigone and the fixed part of bladder were never involved. When cystoscopy was carried out with a flushing instrument, petechial spots appeared on the affected areas throughout the bladder. These spots would bleed on further bladder dilatation, and sometimes the mucosa was seen to split.

Conservative therapy, apart from dilatation, was not effective. Ureterosigmoidostomy was performed 10 times, with 2 deaths; the surviving patients obtained complete relief. Ileocystoplasty was carried out 3 times, but its value is difficult to assess. It appears that either the stoma has to be very wide or extensive partial cystectomy has to be performed for relief of symptoms. The differential diagnosis is from tuberculous and other forms of chronic cystitis, and carcinoma of the bladder. Hunner's ulcer is only one form of chronic interstitial cystitis. The etiology is still unknown, but the possible causes are discussed. It is not likely to be infective, but may be due to hormonal influences and may be partly psychosomatic.

Analysis of 200 Cases of Carcinoma of the Prostate Treated Conservatively. E. J. Satter and J. B. Wear. Wisconsin M. J. 57:327-329 (Sept.) 1958 [Madison].

The authors report on 100 patients with carcinoma of the prostate, who were subjected to orchiectomy and treated with Stilbestrol at the University Hospitals in Madison, Wis., during 1941-1942. Results of treatment in this group of patients ("treated group") were compared with those in another group of 100 patients with carcinoma of the prostate who were subjected to transurethral resection only ("untreated group"). The youngest patient in the untreated group was 47 years old and the oldest 87; the average age of this group was 69.9 years. The patient surviving longest in the untreated group lived 9 years, and the patient surviving longest in the treated group lived 15 years. The average life span of the patients in the untreated group was 22 months after establishment of diagnosis; the survival time of the patients in the treated group was 56 months from the time diagnosis was made. The survival time was best in the 70-to-79-year-old patients in the untreated group and in the 60-to-69-year-old patients in the treated group. The 80-to-89-year-old patients in the treated group lived 32 months longer than those in the untreated group. This indicates that age is no contraindication to the institution of orchiectomy and the administration of Stilbestrol for the treatment of carcinoma of the prostate. Eight of the patients in the treated group lived 10 years or longer. Treated patients, 70 to 75 years old, lived half of their normally expected life span, and patients, 75 to 85 years old, lived 75% of their normally expected span. The total of added years of adult life in the treated group, as compared with the untreated group, was 283 years.

OPHTHALMOLOGY

Recovery of Toxoplasma from a Human Eye. M. J. Hogan, P. A. Zweigart and A. Lewis. A. M. A. Arch. Ophth. 60:548-554 (Oct.) 1958 [Chicago].

The authors recovered from the enucleated eye of a 20-year-old man a strain of Toxoplasma organisms which exhibited low virulence for animals. The patient had a quiescent disease up to the age of 12 years. The significance of a chorioretinal scar in the macula of the right eye, which was discovered at the age of 1½ years, was not apparent to the physician or the family. At the age of 12 years the patient had a sudden diminution of vision in his good left eye, which showed a heavy vitreous haze and an indistinct massive yellowish area of inflammation extending from the disk to the temporal periphery. Roentgenograms of the skull showed calcifications. The neutralizing antibody test and the skin test were positive, and a diagnosis of congenital ocular toxoplasmosis was made. Five months after the onset the vitreous haze in the left eye had cleared so that vision was 20/70. Two and one-half years later the lesion was fairly well healed, leaving extensive scarring and pigmentation of the entire temporal fundus. The vision was 20/100. For several years relapses occurred in this eye, so that the vision was lost. The eye became divergent and hypotonic, a cataract developed, and the eye started to shrink. The patient requested enucleation, which was done. The dye-test titer one year after enucleation was 1:16, and the skin test was still positive.

The chorioretinal tissue from the back of the enucleated eye was ground in a mortar, diluted with sodium chloride solution, and inoculated intraperitoneally into 4 mice. The mice did not show signs of illness, and 3 weeks later their brains were removed, ground, and inoculated intraperitoneally into 4 other mice. Six days later these mice showed some signs of illness, and in a small amount of aspirated peritoneal fluid a few organisms were found which strongly resembled those of the Toxoplasma genus. Other mice were given inoculations of this fluid; 8 days later the animals became ill, and extracellular Toxoplasma organisms were found in their peritoneal fluid. Subinoculations were continued on mice, guinea pigs, and rabbits. The culture studies showed that the Toxoplasma strain originally recovered from the enucleated eye and designated MF strain offered a distinct contrast in virulence to the RH strain isolated and cultured from the eye of an adult by Jacobs and to the strains obtained from persons with severe systemic infections. This finding supports the concept that some cases of inapparent congenital toxoplasmosis, with late exacerbations of the disease, are caused by Toxoplasma strains of low virulence. In many cases of congenital toxoplasmosis the disease is extremely mild and is unrecognized until a late flare-up occurs. The isolation of Toxoplasma organisms from the patient's eye 20 years after birth shows the great persistence of these organisms in pseudocyst form in the tissues, despite the low virulence of the strain.

Ocular Toxoplasmosis: The XIV. Jackson Memorial Lecture. M. J. Hogan. Am. J. Ophth. 46:467-494 (Oct.) 1958 [Chicago].

According to Hogan, the acute manifestations of congenital toxoplasmosis are well established and include chorioretinitis, encephalomyelitis, and visceral inflammation. Ocular toxoplasmosis may be overlooked in an apparently healthy child until attention is directed to the eyes by the development of a strabismus, by detection of amblyopia in one or both eyes during a routine eye examination, or by the development of increased blurring due to a late relapse of the chorioretinal inflammation. The author reports on 36 children with congenital ocular toxoplasmosis, whose ages ranged between less than 6 months and up to 12 months at the onset of the disease. Seven of the 36 patients showed evidence of cerebral calcification which could be considered to be toxoplasmatic; the condition was unilateral in 11; a late relapse of the congenital infection occurred in 12 patients; and strabismus was the first and most common eye complaint in 20 patients. Nine patients had positive results of dye tests and negative results on skin tests, indicating that the skin test is less reliable for diagnosis than the dye test. Nine patients had dye-test titers in excess of 1:512, and 13 had titers between 1:128 and 1:512. In addition to the 36 patients with congenital toxoplasmosis, there were observed 4 others with a late relapse of congenital toxoplasmatic infections. Toxoplasma organisms were isolated from the enucleated eye of one of these patients 20 years after birth. [The case of the latter patient is reported in detail in the preceding abstract.]

Ocular inflammation rarely occurs during the course of acute postnatally acquired systemic toxoplasmosis, although some cases have been reported. In patients with uveitis, questionable enlarged lymph nodes should be excised for microscopic and cultural studies. The methylene blue tests performed on patients with uveitis in various age groups showed 35% of the serums to be positive in a titer of 1:16 or higher, as compared with a 25% incidence in a miscellaneous group of patients with eye diseases other than uveitis. The correlation of results of the methylene blue test and the toxoplasmin test in 617 patients with uveitis revealed that 198 (32%) had positive results from the dye test and 141 (23%) had positive results from the skin test. Forty-eight per cent of the patients with chorioretinitis reacted positively to the dye test and 36% reacted positively to the skin test. This can be compared with 25% and 18% of the normal population in this area. The various skin tests on 1,241 patients with uveitis and on a miscellaneous group disclosed that about 40% of the patients with chorioretinitis and 18% of the patients with iridocyclitis had positive reactions to toxoplasmin tests. In this same group 43% of those with chorioretinitis and 23% of those with iridocyclitis had positive dye-test titers. The percentage of the incidence of positive dye and skin tests in the iridocyclitis group was the same as in the control group. The cases of 5 adult patients, between the ages of 32 and 53 years, with acquired ocular toxoplasmosis have been reported in detail; 2 of these were associated with acute systemic infections. Treatment with pyrimethamine (Daraprim) and sulfadiazine in patients with acquired ocular toxoplasmosis was found to be disappointing, but further studies seemed to be warranted.

Angiomatosis Retinae, Eleven Years After Diathermy Coagulation. D. Vail. Am. J. Ophth. 46:525-534 (Oct.) 1958 [Chicago].

The author reports on a 40-year-old woman with angiomatosis retinae (Hippel's disease), who was operated on for a typical angioma in the left eye. The preoperative vision in this eye was 20/70. With the patient under intravenously administered Pentothal sodium anesthesia, the sclera over the site of the lesion between the 3-o'clock and the 4-o'clock position was exposed, and a single ignipuncture was made with a diathermy needle, 1.5 mm. long (40 ma. for 4 seconds). After ophthalmoscopic verification of the accuracy of the first puncture, 7 more ignipunctures were made around it. The scleral area covered was roughly 3 mm. in diameter. Ophthalmoscopic examination showed that the involved area was "cooked," white, and edematous, so that the outline of the cherry-red tumor could barely be seen. There was no intraocular hemorrhage. Recovery was uneventful. A follow-up examination 11 years after the operation showed that the corrected vision in the eye operated on was 20/20. The scar in the fundus of the eye showed slightly more pigmentation. There was no evidence of recurrence of the original angioma or the development of new ones. The cases of 38 patients with angiomatosis retinae treated by electrocoagulation were collected from the literature.

e ages of the patients ranged from 7 to 40 years. Nine of the 38 patients had both eyes operated on. Of the 47 eyes operated on, 33 (70%) were successfully cured, 6 were improved (eyeball saved, poor or little vision), and 8 were complete failures.

Angiomatosis retinae (Hippel's disease) and its systemic counterpart (Lindau's disease) are disease entities now firmly established in medicine. They are probably more common than supposed. Neurologists and neurosurgeons may miss the ocular lesions; ophthalmologists, the systemic ones. Thus, teamwork is essential. Angiomatosis retinae can be divided into 4 stages of progression during its relentless evolution. Stage 1 consists of one or more dilated and tortuous veins, more or less parallel, running usually to the peripheral and preequatorial areas of the retina. They terminate in a circumscribed tumorous area (the angioma) which may be single or, much more rarely, multiple. Stage 2 consists of retinal hemorrhages, but especially of a deposit of flaky lipid exudates scattered in the various layers of the retina. Stage 3 consists of massive exudation and retinal detachment, and stage 4 is terminal with uveitis, absolute glaucoma, and loss of the eye. Of the 47 eyes operated on, the disease was in stage 1 in 10, in stage 2 in 21, and in stage 3 in 9; the stage of the disease was not specified in the remaining 7. Stages 1 and 2 are the most favorable for surgery, although the operation was considered successful in 4 of the 9 eyes operated on early in stage 3. Mild surface diathermy coagulation followed by pinpoint ignipunctures into the tumor itself seems to offer the best prospect for success. If the tumor is destroyed, the feeder vessels shrink in size and lose their tortuosity. The lipid deposits disappear within one year thereafter. If they do not disappear, it presumably means that the tumor has not been destroyed or new ones have developed. The greatest hazard is hemorrhage into the retina, choroid, or vitreous. For this reason diathermy should be applied with the weakest current capable of doing the job and under frequent ophthalmoscopic control. Direct coagulation of the tumor by diathermy or similar agents gives far better and more certain lasting results than those reported to be obtained by roentgen-ray or radium irradiation.

THERAPEUTICS

Pyrimethamine in the Treatment of Polycythemia Vera. J. W. Frost, R. Jones Jr. and U. Jonsson. South. M. J. 51:1260-1265 (Oct.) 1958 [Birmingham, Ala.].

Pyrimethamine (Daraprim) was given to 14 patients with polycythemia vera for periods varying from 3 to 26 months. Three of the 14 patients received 2 courses of the drug, so that a total of 17 courses of treatment were given. The drug was given by mouth in doses of 25 to 100 mg. daily until the red blood cell count fell to normal limits or below. Treatment then was continued with a reduced dose as maintenance therapy in some patients; in other patients administration of pyrimethamine was continued with the same dose and folic acid was given concurrently in order to determine whether the effect of pyrimethamine on the formed elements of the blood could be reversed by folic acid.

In 11 of the 14 patients there was a fall in hemoglobin level, hematocrit, and red blood cell count. The response to the drug occurred slowly over a period of 1 to 5 months. At the same time there was usually relief of symptoms and reduction in the size of the spleen, when this organ was enlarged. In 9 of the 14 patients the disease was controlled by maintenance therapy for periods ranging from 6 to 19 months. In several of the patients side-effects of pyrimethamine were observed. These consisted of thrombocytopenia, leukopenia, atrophic glossitis, ulcers of buccal mucous membranes, alopecia, and megaloblastic bone marrow changes. These side-effects were never serious and could be reversed by folic acid even with continued pyrimethamine administration. The reversal of all demonstrable biological effects of pyrimethamine by concurrent administration of folic acid indicates that its therapeutic effects in polycythemia are entirely due to its function as a folic acid antagonist. Despite some disadvantages, the drug can be used to control polycythemia satisfactorily in most patients.

Meprobamate Idiosyncrasy: Report of a Case and Review of the Literature. N. D. Charkes. A. M. A. Arch. Int. Med. 102:584-593 (Oct.) 1958 [Chicago].

Meprobamate (Miltown or Equanil) has been in use for several years. Reports on toxic effects have been scattered. One death has been reported. This communication presents a case of meprobamate idiosyncrasy, with skin biopsy and skin testing. It reviews the published reports to date and discusses possible etiological factors in the pathogenesis of the anaphylactoid reaction. The records of more than 6,500 patients have been summarized to date. Twenty-three cases of attempted suicide and 113 cases of idiosyncrasy have been reported. In one-third of the 113 cases of idiosyncrasy the reaction began within 8 hours of commencement of drug therapy, and all reactions, except in 2 patients, had occurred by the end of the first week. The earliest response was within 15 minutes. The reaction had not been seen in any suicidal attempt, so that excessive dosage was not a factor in precipitating it.

In meprobamate idiosyncrasy the rash was erythematous, maculopapular, or urticarial, or a combination of these, as in the case reported here, and may resemble a "boiled lobster." Vesicular and pustular eruptions have been noted occasionally. The rash was most prominent in the groins, inner thighs, buttocks, chest, axillas, and antecubital and inframammary folds; fixed eruptions have been seen. Petechiae were noted in 16% of the cases, almost always nonthrombocytopenic. Ecchymoses were rare, and the only patient with overt bleeding had aplastic anemia. The Rumpel-Leede test of capillary fragility was always positive in cases of purpura. A prominent and often distressing symptom in one-fifth of the cases was pruritus; however, many patients complained only of "burning" or a sensation of warmth. Other symptoms included anorexia, nausea, vomiting, diarrhea, yawning, headaches, chills, and fever, with temperatures of 101 to 103 F (38.33 to 39.44 C). Dizziness, fainting, hypotension, or shock occurred in almost 15%, and a few patients reacted with asthma, ectopic cardiac rhythms, numbness of the legs, emotional upsets, or mental confusion. A prior history of drug or pollen allergy was elicited in only a small number of patients, but, whereas the anaphylactoid reaction rate was only 0.5% for the group of 6,500 as a whole, it was 10 times as great for patients with known allergies.

Some investigators attempted to prove that the reaction was due solely to meprobamate by the administration of one tablet (400 mg.) some time later. This is a dangerous practice and should not be attempted merely to satisfy the curiosity of the clinician. Twenty-eight of the 30 patients who were given another tablet responded with a reaction which was frequently more violent than the original and which in several cases was accompanied by severe shock. At best, this second reaction lasted longer and responded more slowly to steroid therapy than the first. The most important step in the treatment of the anaphylactoid reaction is withdrawal of meprobamate. Indirect evidence is adduced implicating meprobamate as a histamine-liberating agent in certain patients.

Topical Application of a Solution of Pyrazinamide for the Treatment of Tuberculous Empyema. G. Costa and E. Moretti. Minerva med. 49:3269-3271 (Aug. 29) 1958 (In Italian) [Turin, Italy].

A solution of pyrazinamide was introduced topically twice a week for a period of 70 to 180 days in 18 patients with tuberculous empyema. Pyrazinamide treatment was given concomitantly with collapse therapy to 5 patients and after discontinuance of collapse therapy to 9 patients. Primary spontaneous pneumothorax was present in 2 patients. The first dose of pyrazinamide, consisting of 20 cc. of the solution, was followed by doses of 40 cc. Prednisolone was used as an adjunct to pyrazinamide in treating 5 patients in whom tuberculous empyema developed during collapse therapy. A dose of 100 mg. of isoniazid was combined with pyrazinamide in 6 patients with the chronic type of the disease, who had already been treated with and became refractory to isoniazid. Pyrazinamide brought about disappearance of effusion and made possible reinstitution of an efficacious collapse therapy in 5 patients in whom the disease was present during the artificial pneumothorax. Of 9 patients with tuberculous empyema treated with pyrazinamide after termination of collapse therapy, 4 patients obtained temporary relief for 2 months, 4 patients obtained no benefit, and the effusion turned from purulent into serous in 1 patient. Temporary improvement for 1½ months was observed in one patient with primary spontaneous pneumothorax, and complete healing of the pleural cavity was obtained in one patient.

The best results with pyrazinamide were observed in patients who had not previously received any chemotherapy and in those in whom the disease was of recent date. The combination of pyrazinamide and isoniazid was only slightly efficacious. A mild malaise, chest pain, and fever episodes were the most common side-effects noted at the onset of treatment with pyrazinamide. Five or 6 months after the onset digestive disorders developed in some patients who obtained only temporary relief with the drug. The authors suggest treatment with pyrazinamide in all instances in which benefits from other antibiotics have been exhausted. It may also be used as an adjunct to other antibiotics for the treatment of chronic types of the disease.

Iproniazid (Marsilid) in Angina Pectoris. A. M. Master. Am. Heart J. 56:570-582 (Oct.) 1958 [St. Louis].

Fifty-eight men and 16 women, between the ages of 40 and 79 years, with typical and severe angina pectoris were treated with iproniazid (Marsilid) for periods ranging from 1 week to 5 months. Each patient was given 50 mg. of the drug 3 times daily after meals. In an attempt to prevent the occurrence of peripheral neuritis and dryness of the mouth, 25 mg. of pyridoxine were given with each dose of iproniazid. Complete relief of pain was obtained by 13 patients and almost complete relief by 28 patients; improvement was doubtful in 4 patients, and 29 were therapeutic failures. Five of the 41 patients who obtained relief and 1 of the 29 patients who did not were in "status anginosus" when the treatment was instituted. Neither the resting electrocardiogram obtained from the patients nor the results of the Master "2-step" test to which they were subjected were altered in the course of the treatment with iproniazid. These findings suggested that the fundamental coronary disease was not altered. The precise mechanism of the relief of pain by iproniazid is unknown. The relief obtained can possibly be explained by cerebral stimulation, with uplift of mood, and increase of the pain threshold. There may be a direct effect on the autonomic nerve connections between the heart and the spinal cord and brain.

Severe side-reactions made withdrawal of the drug necessary in 57 patients. In some patients the drug was tolerated for only one month or less. The side-effects were mainly gastrointestinal, genitourinary, and cardiovascular; the latter included dizziness, fall in arterial pressure, and syncope. Three patients sustained an attack of acute coronary insufficiency in the course of the treatment, and acute coronary occlusion occurred in 2 additional patients, 1 of whom died. Less common complications were evidences of cerebral stimulation, peripheral neuritis, dryness of the mouth, hepatitis, and significant gain in weight. The fall in blood pressure is probably a factor in syncope and in attacks of acute coronary insufficiency. It may possibly be a factor in the precipitation of coronary occlusion. The physical overactivity associated with euphoria, excitement, and loss of pain may cause coronary insufficiency. For these reasons, the patient receiving iproniazid should be supervised closely. Blood pressure should be measured in the standing position. On the other hand, glyceryl trinitrate (nitroglycerin) should never be taken by the patient except in the sitting or recumbent position. In view of the numerous side-effects, some of which are potentially dangerous, further therapeutic trials with iproniazid should be carried out only in hospitals and by research teams.

Fluoxymesterone Therapy in Advanced Breast Cancer. B. J. Kennedy. New England J. Med. 259: 673-675 (Oct. 2) 1958 [Boston].

Investigations revealed that the halogenated androgen, 9α-fluoro-11β-hydroxy-17α-methyltestosterone, or fluoxymesterone, is an effective agent in the treatment of advanced breast cancer. It is an androgenic, anabolic hormone that may be administered orally. Fifty-six patients with advanced breast cancer were treated with it over a 2-year period: 48 of these patients had not received previous hormone therapy, and 8 had previously been treated by surgical hypophysectomy. Of the 48 patients, objective regressions of metastatic breast cancer occurred in 18 and subjective improvement in 25. The quality of improvement in the cancer was similar to that previously noted with testosterone propionate. The frequency of objective improvement would appear to be slightly greater than that with testosterone propionate. The obvious smallness of the series demonstrates the need for greater experience to increase the validity of the figure, but it is apparent that patients demonstrating regressions have survived longer than the nonresponding group. Of the 56 patients treated, 27 remain alive.

Observations on the side-effects of fluoxymesterone have revealed masculinizing changes and erythropoietic changes, as noted with other androgenic compounds. In the doses employed, though, the degree of hirsutism and acne has been less than that with testosterone propionate, and the degree of hoarseness, oily skin, and alopecia has been the same as with testosterone propionate. Increase in libido, encountered with testosterone propionate, did not occur with fluoxymesterone. Evidence of hypercalcemia developed in only 7% of the patients after the onset of fluoxymesterone therapy. The ease of administration, the less distressing masculinizing effects, and the antitumor effect attained are such that fluoxymesterone may be considered the androgen of choice in the treatment of advanced breast cancer. Androgenic hormones are most effectively employed in postmenopausal women with osseous metastases. Objective improvement occurs in about 25% of these patients, with a lower rate of response in patients with soft-tissue lesions.

PATHOLOGY

Primary Malignant Melanoma of the Oral Cavity: A Review of 105 Cases. A. P. Chaudhry, A. Hampel and R. J. Gorlin. Cancer 11:923-928 (Sept.-Oct.) 1958 [Philadelphia].

Primary malignant melanoma of the oral cavity is a rare tumor, the authors having found records of only 105 cases, including 2 previously described by themselves. This review is based chiefly on 93 cases, since the other 12 lacked adequate description. Primary malignant melanoma of the oral cavity occurred nearly twice as frequently in men as in women. This finding is in contrast to that for malignant melanoma of the skin, which affects both sexes equally. The youngest patient in the present study was 22 years of age and the oldest, 90 years; but in nearly 90% of the reported cases the patients were more than 30 years of age, and in 75% more than 40 years, with a peak in the 6th decade. The site of predilection for the disease was the upper jaw, where 75 (80%) of 93 cases originated. The other sites of involvement, in order of frequency, were the lower jaw, cheeks, tongue, and floor of mouth. In nearly 30% of the cases there was melanin pigmentation at the site at which the neoplasm originated. This pigmentation had appeared from a few months to several years before the tumor.

Malignant melanoma of the oral cavity has been reported in all races. In more than half of the 93 cases clinical evidence of lymph node metastases was recorded. In 19 cases there was clinical or roentgenologic evidence of generalized metastases. Of the 61 patients followed, 51 died of the disease. In 24 cases the survival period averaged 18½ months after diagnosis. There were only 3 patients who lived for more than 5 years. The authors feel that, in view of the serious prognosis of the disease, early recognition of the lesion and institution of radical surgery are desirable. The appearance of melanin pigmentation in the mouth and its increase in size and in depth of color should be viewed seriously.

BOOK REVIEWS

Pathophysiology in Surgery. By James D. Hardy, M.S., M.D., F.A.C.S., *Professor and Chairman, Department of Surgery and Director of Surgical Research, University of Mississippi Medical Center, Jackson.* Cloth. $19. Pp. 704, with 278 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1958.

This text, on the physiological disturbances observed in patients who are classified as presenting surgical conditions, goes beyond simple surgical patients and includes those presenting diseases for which surgical therapy may not be considered. In a limited space, adequate critical review is impossible. The book begins with a consideration of the physiology of injury and proceeds to fluid balance, surgical nutrition, the physiology of connective tissue, microbiology, burns, cancer, radiation, enzymology, aging, liver and biliary tract, pancreas, blood transfusion, alimentary tract, circulatory system, lungs, anesthesia, endocrine system, nervous system, infancy, and urologic considerations of special interest. In an attempt to emphasize a "surgical slant" some expressions employed might seem far-fetched, such as "surgical enzymology," the heading of one relatively short paragraph; "surgical aspects of aging," which in essence conveys the idea of danger in operating on patients whose vitality is reduced because of age; and the expression "surgical nutrition." It would seem after all that nutrition is nutrition and enzymology is enzymology.

The text is written in a conversational rather than formal style. The author attempts a wide coverage, sometimes exceeding what might appear the limits of the subject as indicated by the title. This may lessen a reader's confidence in what is related, as, for example, his confidence in what one man says in the chapters on the general physiological reaction of the patient to injury, the question of fluid and electrolyte balance, "physiological considerations in cancer," and urologic considerations of special interest. These are separate areas in which much work has recently been done, and a modern text should include sound critical evaluation based on thorough first-hand knowledge. Further perusal reveals some rather important gaps of which the author may not be aware. For example, only one paragraph and one sentence is devoted to the formation of gallstones. No mention is made of the classical studies of Phemister on calcium carbonate stone formation related to intermittent and complete cystic duct obstruction. In the consideration of gastric physiology much attention is paid only to hypersecretion and acidity. The all-important physiologic aspects of achlorhydria receive only one sentence and the word "achlorhydria" does not even appear in the index. In the discussion on the pancreas clinical reports with important implications for pancreatic physiology are not referred to. For example, the fact that in long-range survivors who had an excision of the duodenum and head of the pancreas with occlusion of the external secretion—this is a different situation than after total pancreatectomy—there may be no appreciable physiological disturbances, and that in human diabetics who had a total pancreatectomy the diabetes is not appreciably if at all aggravated.

Here and there one encounters obvious inaccuracies such as the statement that subtotal gastric resection "first performed by Theodor Billroth in 1881 was based upon the physiologic facts that hydrochloric acid is secreted by the cells of the fundus." Billroth performed a limited pylorectomy for cancer and was never concerned with gastric resection for ulcer since he was ignorant of the acid-ulcer concept. Also this is probably the first occasion where in a physiological treatise reference is made to a fiction "best seller" to help emphasize a point (page 602, "Point of No Return," J. P. Marquand). Probably the best feature of the work is the large number of diagrams, line-drawings, tables, graphs, and photographs. Many appear original and many tell the story without recourse to the text. Here again, however, some questions may arise, as in figure 93, which purports to have settled the question about the best method for alimentery tract reconstruction after pancreatoduodenectomy. Experienced surgeons would not agree with what is shown. The volume is well bound, the paper of high quality, the type is large, facilitating ease of perusal, and the bibliographies are fairly complete. The work is interesting and would be especially useful for advanced students, interns, residents, and Board examination candidates.

Hearing Therapy for Children. By Alice Streng, M.A., and others. Second edition. Cloth. $6.75. Pp. 353, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W. C. 1, England, 1958.

This is a somewhat revised edition of the 1955 publication of the same title. It purports "to include for the first time in one book the special skills and knowledge needed by members of those professional groups who work with hearing-handicapped children." Although this is a noteworthy

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

purpose, it would be difficult to include in one book all phases of such work and, although presented as a single cohesive work, the book consists of two parts. The first is a general discussion of the problem of deafness in children, causes and treatment of hearing loss, audiometry, and hearing aids. The rest of the book is devoted to specific techniques in the educational management of hard-of-hearing and deaf children. The first part should be helpful as an orientation to the field of pedoaudiology and the second half should be of particular interest and benefit to speech and hearing therapists and teachers of deaf children. The book contains good lists of references, particularly at the end of the chapters dealing with the education of children with impaired hearing. Each chapter has adequate figures and photographs. A few changes could have been made in a second edition which apparently were overlooked; for example, in the chapter on hearing aids, a discussion of the vacuum tube instruments preceded mention of transistor aids, in spite of the fact that practically all hearing aids now dispensed are of this type. The same chapter refers to the approval of hearing aids by the Council on Physical Medicine and Rehabilitation of the American Medical Association, a practice which that body discontinued several years ago. Despite certain shortcomings of this book, most of which may be due to the fact that there are five authors, its value to audiologists and teachers of hearing impaired children is apparent. Less obvious is its value to the general physician or even the otologist.

Circulation: Proceedings of the Harvey Tercentenary Congress Held on June 3rd-June 8th 1957 at the Royal College of Surgeons of England, London. Edited by John McMichael, M.D., F.R.C.P., F.R.S., Professor of Medicine, University of London, London. Cloth. $10.50. Pp. 503, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

The first part of this interesting volume consists of a series of historical essays dealing with the life of William Harvey and related material. These are presented by Kenneth Franklin, Frederick Willius, John F. Fulton, Charles Dodds, Geoffrey Keynes, Tom Hare, and others. The second part deals with a review of present knowledge of the circulation. Space does not permit a complete listing of titles and authors, although this should whet the appetites of all physicians, especially those with special interest in the circulation. To list a few of the participants, they include George Pickering, Louis Katz, Paul Wood, C. Heymans, Gustav Nylin, Donald Gregg, Claude Beck, Andre Cournand, Russell Brock, MacDonald Critchley, Seymour Kety, E. H. Botterell, James Learmouth, Stanley Bradley, and Russell Brain. The broad subjects covered include the role of the heart in circulation, hemodynamics, coronary circulation, pulmonary circulation, results of cardiac surgery, cerebral circulation, splanchnic circulation, and peripheral circulation.

In general the material is well presented although, as with all symposiums, the quality is uneven. There is one profound error of omission in this presentation. While the physiological presentations are complete, the therapeutic aspects discussed are almost entirely surgical. The uninitiated may be led to assume that these distinguished investigators believed that the only substantial progress in the understanding or the treatment of cardiovascular diseases has been by our surgical confreres. In actual fact, the number of patients whose problems are clarified or conditions benefited by the use of digitalis and the many other cardiac drugs, the anticoagulants, and the antihypertensive agents, to mention a few important groups, far exceeds the numbers of patients who will ever come to surgery for their cardiovascular conditions. Therefore, if treatment is considered at all, a more balanced presentation would be desirable. Nevertheless, one cannot but feel that William Harvey would have been pleased that such a distinguished group of scientists was gathered in his honor 300 years after his death and that their words will be available to others throughout the world. This is indeed a test of the durability of one's work.

Ciba Foundation Colloquia on Ageing, Volume 4: Water and Electrolyte Metabolism in Relation to Age and Sex. Editors for Ciba Foundation: G. E. W. Wolstenholme, O.B.E., M.A., M.B., and Maeve O'Connor, B.A. Cloth. $8.50. Pp. 327 with 85 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W. 1, England, 1958.

This small volume on the relationship of two subjects in the forefront of medical interest, viz., aging and electrolyte metabolism, contains 18 essays with appended discussions by participants in a colloquium sponsored by the Ciba Foundation. Although part of the book deals with electrolyte relationships to age and sex, most of it is concerned with more general aspects of the subject ranging from the genetic control of electrolyte metabolism in the erythrocyte to the effects of severe magnesium deficiency. The participants were eminent authorities in the field whose discussions, based on their own studies, add inestimably to the value of the book. The book should prove of interest to research workers in the field of electrolyte metabolism and its hormonal aspects in relation to age and sex. It is well printed and adequately illustrated, with the more pertinent references to the literature appended to each chapter.

QUESTIONS AND ANSWERS

ADULT IMMUNIZATION SCHEDULES

To the Editor:—*Please suggest optimum intervals for immunization protection of adults against the following diseases (with adequate initial immunization series): smallpox, diphtheria, tetanus, typhoid, influenza, and poliomyelitis.*

Nelson M. Taylor, M.D., Grosse Pointe, Mich.

Answer.—Assuming that adequate initial immunization series have been given to protect against the diseases listed, the optimum intervals for immunization protection of adults are as follows: smallpox, vaccination every three years; diphtheria, immunization not recommended for adults except in cases of Schick-negative reaction in a person exposed to special risks; tetanus, booster dose at the time of each injury where danger of tetanus exists, with reinjection in the absence of an injury at intervals of no longer than five years; typhoid, reinforcing injections every three years; influenza, injection every year for risk cases (as in old or chronically ill persons); and poliomyelitis, not enough time has elapsed yet to learn about the duration of the protection conferred by the Salk vaccine, but a fourth dose, given not earlier than one year after the third dose, could be administered to individuals exposed to special risks. It should be understood that these are general guiding schedules which vary according to the circumstances. For instance, for persons traveling to areas where smallpox is endemic, revaccination at intervals as short as six months may be desirable. The same is true for persons living in typhoid endemic areas, who should get a booster dose every year.

TEST FOR CARBON DIOXIDE COMBINING POWER

To the Editor:—*What is the physiological reason for equilibrating the blood with carbon dioxide in obtaining the value for carbon dioxide combining power?* *M.D., New York.*

Answer.—The carbon dioxide combining capacity of blood plasma represents the capacity of the hydroxyl ion in the blood plasma to combine with carbon dioxide, at the usual alveolar air tension of about 40 mm. Hg, to form bicarbonate. Introduced by Van Slyke and Cullen in 1917, this procedure consists in determining the carbon dioxide content of plasma that has been equilibrated with normal alveolar air, which contains about 5 to 6% of carbon dioxide and therefore has a tension of about 40 mm. Hg. From this value, the dissolved carbon dioxide, or carbonic acid, is subtracted, so that the difference represents the bicarbonate content. This type of determination is one measure of the hydroxyl content or "alkaline reserve" of the body. Among the advantages of this procedure is the fact that it does not require collection of blood anaerobically under oil or mercury, as any escape of carbon dioxide from the plasma during centrifuging or standing is counteracted in the actual determination by the equilibration. Among its disadvantages are that equilibration with alveolar air requires additional equipment and is time consuming and laborious; that it does not measure directly the concentration of either bicarbonate or total carbon dioxide in the circulating blood; and, most important, that it does not yield information about those acid-base derangements in which the ratio of bicarbonate ion to dissolved carbon dioxide at the actual carbon dioxide tension, rather than the concentration of bicarbonate ion at 40 mm. Hg, is the determining factor. Consequently, it has become much more common and acceptable to determine the carbon dioxide content of the plasma or serum from blood that has been collected under oil and centrifuged with precautions to prevent loss of carbon dioxide. The relationship between carbon dioxide content, expressed in millimoles per liter, carbon dioxide tension (p), expressed in mm. Hg, and the pH is contained in the well-known Henderson-Hasselbach equation:

$$\text{pH} = 6.10 + \log \frac{\text{mM. CO}_2 - 0.0301\ p}{0.0301\ p}$$

For example, in a case of diabetic acidosis reported in the literature, the carbon dioxide combining capacity was 22.6 vol. % or 10.1 mM. The carbon dioxide content was 5.28 mM. per liter at an actual tension of 11.8 mm. Hg. The pH was, according to the above equation, 6.10+log 13.8 or 7.24. The Henderson-Hasselbach equation and determination of carbon dioxide content also permit a readier understanding of other acid-base disturbances. To illustrate, in a case of respiratory overventilation reported in the literature, the carbon dioxide combining capacity of the arterial serum was 40.9 vol. % or 18.4 mM., not clearly abnormal. Yet, the plasma carbon dioxide content was 31 vol. % or 14 mM. per liter, the carbon dioxide tension in the circulation was 14.6 mm. Hg, and the pH was 7.59. In general, the determination of the plasma carbon dioxide content, that is, the sum of the bicarbonate

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

ion and the dissolved carbon dioxide at the actual carbon dioxide tension existing in the arterial circulation, may give more distinct and precise clues to the presence of acid-base derangements than the concentration of bicarbonate ion at 40 mm. Hg (the carbon dioxide combining capacity).

"AIR PLATES" AND CONTROL OF HOSPITAL INFECTIONS

To THE EDITOR:—*In an attempt to control staphylococcic infections in the hospital, the administrative and surgical staffs have requested the use of "air plates" throughout the operating room suite. It has been difficult to find much helpful information concerning a standard procedure for collecting such specimens and interpreting the findings. Specifically, what is the optimum time interval for exposure of the plates, how should the total colony counts be determined, and how extensive an attempt should be made to identify the colonies present? Should an attempt be made to identify all the colonies on each plate?*

William D. Kelly, M.D., Elmira, N. Y.

ANSWER.—The exposure of open Petri plates (blood agar plates or plates containing a comparable good nutrient) at various locations in the operating room has not been standardized. The plates are uncovered at selected locations throughout the room and are allowed to remain exposed to the air for periods ranging from one-half to one hour. On occasion, the plates are exposed in the operating room during different periods of activity and inactivity for comparative information. This procedure may detect bacteria or dust particles which "fall out" and inoculate the medium, and it is more qualitative than quantitative. Bacteria present in air currents are not detected by this method. The slit air sample provides more quantitative results, but the initial cost of the equipment is expensive. A less expensive technique is available in an all-glass impinger apparatus which is reported to be quite satisfactory. With this technique, air is passed through sterile saline solution or broth and quantitative determinations are obtained.

There is no standard of interpretation. The total number of colonies on a plate cannot serve as a true index, since it is only a rough estimate in view of the limitations of the collecting procedure. Laboratory workers should be familiar with the saprophytic forms that might be encountered in the area in question and should be able to differentiate them from potential pathogens, such as staphylococci. Although identification of all colonies obtained in a study of air in an operating room is expensive and laborious, in an epidemic it may be advantageous to make such a specific identification. Air counts may be used more profitably as a device to educate operating-room personnel in the proper techniques to be used in reducing the bacterial counts of the air. Since epidemic strains of staphylococci are carried in the upper respiratory tract of approximately 10% of hospital personnel, it may be more logical to detect epidemic strains in the carriers among the personnel rather than to search for them in cultures made of the air. To investigate the question of identification, phenolphthalein phosphate might be included in the mediums (Barber and others, *J. Path. & Bact.* 63:57, 1951). This method may be useful if the organism produces coagulase, since this will result in the formation of phosphatase which will split off the phenolphthalein from the phenolphthalein phosphate. Then, if the plate is held over fuming ammonia, the presence of coagulase-positive staphylococci will be shown by a pink color.

The role of the hospital laboratory in a program designed for the control of cross infections within hospitals is an important one. The bacteriologist is often one of the first persons to know of an epidemic situation and can assist in the collection of statistics, check the sterility of supplies, and check the adequacy of sterilization techniques. He is able to store cultures of staphylococci obtained from hospital-acquired infections. These could be of value in the event of an epidemic, since they could aid in determining the specific strain involved in the epidemic and in detecting carriers in the institution.

NEURITIS OF RECURRENT LARYNGEAL NERVE

To THE EDITOR:—*A 55-year-old woman has an idiopathic neuritis involving the left recurrent laryngeal nerve. Every conceivable test has been carried out to determine whether pressure could be exerted on the recurrent laryngeal nerve both in the throat and in the mediastinal region. However, all tests show absolutely negative findings, including tuberculin tests. She has apparently had this condition for two years; this would probably rule out the existence of mediastinal malignancy or a lymphoma. At the present time she is being treated for the resolution of a neuritis of the left recurrent laryngeal nerve. Her chief symptoms are hoarseness and periodic coughing, associated with laryngeal spasm. Surgical exploration of the mediastinal region has been considered. Please give further suggestions. What is the incidence of an idiopathic type of neuritis involving the left recurrent laryngeal nerve?*

S. W. Scorse, M.D., Joplin, Mo.

ANSWER.—A search for the cause of recurrent laryngeal nerve paralysis can sometimes be unrewarding, and the number of "idiopathic" cases has run as high as 30% in one large reported series. Toxic and inflammatory causes may account for an additional 15-20% of cases. In the situation under discussion, the duration of the condition would probably rule out the existence of any malignancy. Barium studies of the esophagus and planigrams of the chest and mediastinal areas might be suggested. If there are no findings other than the isolated paralysis, surgical exploration of the mediastinum would not seem justified in view of the above figures. Fortunately, most of the individuals with unilateral vocal cord paralysis of undetermined cause do develop a good voice eventually, and their coughing episodes and laryngospasm disappear. If voice reeducation is hampered by virtue of the position of the paralyzed cord in partial abduction, some type of plastic procedure can be performed to permit contact by the remaining mobile cord.

Answer.—There is no entity which can be regarded as idiopathic recurrent laryngeal neuritis. Instances occur in which hoarseness develops for no assignable reason, and it is sometimes the case that nothing can be found to explain the condition, either in local, peripheral, or central nervous system disease. It is possible that in an instance such as this the hoarseness may be the first manifestation of disease involving the vagus nucleus (nucleus ambiguus) in the medulla, due to a local cause or to amyotrophic lateral sclerosis. It is also possible that the symptoms may be the result of involvement of a branch of the posterior-inferior cerebellar artery. If there are no other findings beyond those of hoarseness, only time can determine the cause in the presence of negative findings in the present studies.

SILICA EXPOSURE AFTER TUBERCULOSIS

To the Editor:—*If it is possible to generalize, should a man who has had pulmonary tuberculosis adequately treated and whose disease has been declared arrested or cured be allowed to return to silica brick yard work where there is even minimal silica exposure hazard? Also, are there any absolute contraindications to prophylactic aluminum dust inhalation—disregarding the question of its value? Special reference is made to coronary artery disease, bronchial asthma, and arrested pulmonary tuberculosis.*

Fred H. McClain Jr., M.D., Mount Union, Pa.

Answer.—The answer to the first question would have been an emphatic "no" as recently as 10 years ago. It seems from more recent experience, however, that it is safe to allow workers with adequately treated and inactive tuberculosis to return to jobs where the silica dust hazard has been controlled. By "controlled" is meant that the amount of crystalline-free silica dust in the atmosphere is at all times less than 5 million particles per cubic foot (for particle sizes of less than 10 μ). This must be calculated from the total dust count by knowing the free silica content or percentage of a given dust. Numerous U. S. Public Health Service surveys have shown that a recognizable silicosis will not occur in the working lifetime if the silica dust exposure is kept below that figure. Other studies have shown that silica dust exposure per se does not appear to have a deleterious effect on tuberculosis. Sufficient cellular reaction to the silica to be recognizable by chest x-ray studies must have occurred before the reactivating effect becomes apparent. However, where there is any doubt about the silica dust control, the answer to this question still is "no." When such a worker is returned to a job which has good dust control, it is advisable to continue treatment with tuberculosis drugs indefinitely.

The answer to the second question also must be qualified. There is no evidence that aluminum dust would have a harmful effect on coronary artery *disease, but experimental animals with low virulence* tuberculosis have shown slight progression of the disease after aluminum inhalation. There have been only rare cases of such progression in humans. As for bronchial asthma, there has been no recorded experience to this consultant's knowledge. If the proponents of the use of prophylactic aluminum dust are correct in their theory that aluminum inhalation tends to relax bronchospasm, then there should be a beneficial rather than harmful effect with bronchial asthma. Proof of this is lacking, however.

SYMPTOMS OF HYPOGLYCEMIA

To the Editor:—*A thin, 38-year-old man has had spontaneous hypoglycemia since 1951. His blood pressure is 110/72 mm. Hg. Basal metabolic rate is —8% and protein-bound iodine level 5 mcg. per 100 ml. Glucose tolerance findings were as follows: fasting, 110 mg. %; 30 minutes, 60 mg. %; one hour, 60 mg. %; two hours, 58 mg. %; three hours, 64 mg. %; four hours, 68 mg. %; and five hours, 72 mg. %. No sugar was present in the urine. Symptoms of mental confusion, slow mentation, lightheadedness, and negativeness were noted 15 minutes after the glucose tolerance test was begun. These symptoms also occur throughout the day every day and are completely, though temporarily, relieved by ingestion of carbohydrate. One sister has renal glycosuria. A 50-Gm. carbohydrate diet and six feedings per day have not relieved the symptoms. Please suggest further treatment.*

Frank H. Hamilton Jr., M.D., Charlotte, N. C.

Answer.—The questioner does not state the method of blood sugar level determination which was used. If this was the Folin-Wu method or one yielding similar results, then the fasting blood sugar value is within normal limits, although it is a trifle higher than the average. Other values are at a level which might give rise to symptoms of hypoglycemia in a sensitive individual. If the values were obtained by the Somogyi-Nelson or a comparable procedure, then the fasting value is at the upper limit of normal and consistent with "mild" diabetes. The other values are at levels which ordinarily would not give rise to hypoglycemic symptoms. It would be worth knowing at what time during the period of symptoms (which date back to 1951) the glucose tolerance test was done. Was more than one glucose tolerance test carried out, and, if so, were the results quoted typical of those obtained in other tests? Taking the findings in the glucose tolerance test at their face value, one would be doubtful of the presence of an islet cell tumor. The level after an overnight period of fasting is somewhat above, rather than much below, the average normal, and in the third, fourth, and fifth hours after glucose is given there is a steady, though slight, tendency for the blood sugar level to rise spontaneously. It would appear that in this patient the pancreas is unusually responsive to the stimulating effect of carbohydrate. Certainly a low-carbohydrate, liberal-protein diet is indicated with the amount of fat at that level necessary to maintain proper body weight. It is possible that, with frequent administration of carbohydrate during the day to relieve symptoms, the actual amount of carbohydrate taken in 24 hours is much more than the 50 Gm. stated. No mention is made as to whether hypoglycemic episodes have occurred during the night or in other periods of fasting. Unless these have already been carried out, the following measures are suggested: (1) repetition of the glucose tolerance test; (2) observation of the behavior of the blood sugar level after a prolonged fast, up to 24 hours (this could be done by determining the blood sugar level after an overnight period of fasting, continuing to withhold food, and measuring the blood sugar level every two or three hours until a full 24-hour fast has been accomplished); (3) attempts to relieve hypoglycemic episodes by the ingestion of food predominately protein rather than carbohydrate in content; (4) use of daily medication with belladonna and phenobarbital in appropriate doses; and (5) ruling out causes other than hypoglycemia which might be responsible for the symptoms.

TRANSFIXING LUMBOSACRAL JOINTS

To the Editor:—*What is the current feeling about the use of screws through the zygoapophysial junctions of L-4 and L-5, L-5 and S-1, and S-2 to stabilize the lumbosacral spine?*

C. J. Kilduff, M.D., Lancaster, Pa.

Answer.—The use of screws to transfix the facet joints in the lumbosacral area of the spinal column in conjunction with spinal fusion has been accorded some favor during the past 10 years. Reliable qualified orthopedists have used this method and reported their technique. Adequate follow-up studies, which include the use of other techniques as a control, have not yet been published, so far as is known. Thus, evaluation of the use of screws to stabilize this portion of the spinal column as an adjunct in spinal fusion remains difficult. However, in general, the practice appears to be declining, even among those who advocated it originally. Certain complications have arisen, such as impingement of the transfixing screw on the underlying nerve root as well as the usual complications involved in introduction of a foreign body, such as metal, into bone. At best, the use of screws in this manner would be an adjunct to spinal fusion. The screws cannot fix the spinal column rigidly and would function only as a mechanical aid for bone grafts, placed in one of many ways possible, to become solid.

FOOTBALL FOR FOURTEEN-YEAR-OLD BOYS

To the Editor:—*What is the present consensus on 14-year-old boys playing regular football, as opposed to 6-man football, while they are in high school? Some believe that 11-man football should not be played at all in high schools because of the frequency of epiphysial and joint injuries, since the bones are still growing and since an epiphysial injury may well cause retardation of growth in the involved extremity. The particular boy under consideration is in excellent health but is lighter than the average, weighing about 110 lb. (49.9 kg.). He wants to play in the backfield because of his extreme speed, but it is felt that a fast runner being tackled is more likely to receive injuries than a lineman.*

M.D., New York.

Answer.—If the statistics for particular phases of the game are checked, it will be noted that tackling or being tackled accounts for high incidence of the injuries. Comparison of 11-man and 6-man football as far as injury incidence goes indicates that there are fewer sprains, strains, and bruises in the 6-man game but more fractures and other serious injuries. The 6-man game tends to be more open in nature, but the element of tackling still remains and greater momentum is attained. The boy mentioned in the question is certainly not heavy in comparison to some of the players with whom he might compete in high school. Whether such players are carefully matched in terms of age, height, and weight for their play is important in this framework. There has been much dispute about the hazard to the growth areas of the long bones during adolescence in relation to contact sports, particularly football. Different surveys among orthopedic surgeons have elicited varying replies. While there is no dispute about the hazard, many feel that the supervised situation in high school is safer than the sandlot activities in which the interested boy may participate if he is excluded from school participation. The question as to whether a 14-year-old boy, presumably a ninth grader, should participate in tackle football involves more than a few issues. A few years ago, Dr. Thomas Shaffer made a study relating to the evaluation of the high school athlete for participation. He feels that maturity is a vital consideration in such an appraisal.

REGIONAL ILEITIS AND PREGNANCY

To the Editor:—*A 24-year-old woman has a history from early childhood of three or four daily bowel movements with mucus but no blood or cramps. One and a half years ago it was noted that she had lost weight, and on examination anemia, elevated sedimentation rate, and a mass about the diameter of a grapefruit in the right lower quadrant were noted. X-ray studies revealed a fistula in the right lower quadrant connecting the rectosigmoid, the cecum, and a loop of distal ileum. A narrow sinus tract about an inch long, ending blindly, and probably originating from the sigmoid was also noted in the left lower quadrant. Two or three small diverticula were also noted in the sigmoid and descending colon. It was noted on fluoroscopy, with barium enema, that the barium entered the cecum and loop of proximal ileum prior to entering the sigmoid. It was noted on upper gastrointestinal studies that barium entered the rectum within one and one-half hours. The diagnosis of regional ileitis with fistula involving the terminal ileum, cecum, rectosigmoid, and a more proximal loop of distal ileum was made, and operation was considered. However, the patient became pregnant at this time with her first baby, and the decision was deferred. She had an uneventful pregnancy, and during her pregnancy and since then she has had no diarrhea except for occasional mild episodes on aggravation. Her weight level, hemoglobin value, and state of well-being are well maintained. A repeated barium enema (done one year after the original studies) showed the same findings, and the mass in the right lower quadrant has remained about the same size. Is it advisable to perform operation with resection at the present time with a view toward avoiding future flare-ups of the disease and further complications, or should the conservative approach of watchful waiting be taken?*

M.D., New York.

Answer.—If the story had ended prior to the patient's pregnancy, operation would have been the treatment of choice—resection of the distal ileum, separation of the fistula from the sigmoid, and removal of the diseased segment of intestine. It appears that, during pregnancy, there has been a good deal of healing of the inflammatory process in and about the ileum and that the patient is now considerably improved from the standpoint both of her general well being and of her weight and her hemoglobin level. However, the presence of the mass indicates that she still has considerable difficulty. Because of the risk at operation and the high incidence of recurrence of ileitis in this type of individual, the conservative approach of "watchful waiting" is entirely justified. However, if further signs of activity in the fistulous tract occur, resection should be reconsidered.

1918 INFLUENZA EPIDEMIC COMPARED TO ASIAN INFLUENZA EPIDEMIC

To the Editor:—*Please give information on the clinical differences between the European type of influenza (epidemic after World War I) and the Asian type. Are there more cases of nervous disorder—spinal, Parkinsonism, or encephalitis lethargica—with the Asian type of influenza than with the European?*

Gottwald Schwarz, M.D., New York.

Answer.—Compared to the A/Swine influenza pandemic of 1918, the A/Asian influenza pandemic resulted in relatively few fatalities. Excess mortality for influenza and pneumonia in the United States was actually less than that for several other influenza epidemics in the decades since 1918. No other pandemic or major epidemic of influenza has been so severe in terms of mortality as that of 1918. Debate still continues as to whether the deaths in 1918 were due primarily to the virus itself or to secondary bacteria. In 1957 and 1958, only a small number of deaths were clearly due to the virus alone. These deaths were caused primarily by severe hemorrhagic tracheobronchitis and/or pneumonia. The majority of the 1957-1958 influenza-associated deaths were caused by complicating bacterial pneumonia. Most nonfatal cases of Asian influenza were not very different from nonfatal influenza cases in 1918. Symptoms in both pandemics were essentially the same. Fever, headache, malaise, myalgia, cough, and sore throat were most often reported. There appear to have been more severe cases of primary viral hemorrhagic tracheobronchitis and pneumonia and more complicating bacterial pneumonias resulting in death in 1918 than in 1957-1958. Whether most deaths were due to the virus itself or to bacteria is uncertain. In both pandemics, small numbers of cases of influenza encephalitis were reported. More appear to have been reported in 1918, but confirmation was not as possible in such cases then as it is now. It is likely that the A/Swine virus caused no more or no less encephalitis than the A/Asian strain. Encephalitis lethargica (Economo's disease) was something quite different and apparently unrelated to A/Swine influenza, although it did become world-wide after the influenza pandemic in the period just before and after 1920.

SALIVARY GLAND TUMOR

To the Editor:—*A small tumor located right at the anterior capsule near the bone was removed, with the facial nerve and some of parotid gland left. Four days after operation the pathologist reported the tumor to be a mucoepidermoid carcinoma in the upper grade of malignancy with a tendency to metastasize. The patient is over 72 years of age. Is surgery indicated? Should the whole parotid gland have been removed and the facial nerve cut? Should x-ray treatment be given?*

M.D., Georgia.

Answer.—Several general principles are applicable when the surgeon is confronted with a swelling or tumor mass of unknown nature in the parotid area. First, he should consider that the tumor is possibly, as it was in this case, carcinomatous. Second, it should be recognized that, in their early stages, some malignant tumors give no clue that they are in fact malignant. The surgery should be designed to encompass the tumor with a surrounding mass of normal salivary gland tissue. If this can be accomplished without injury to the facial nerve it will suffice in many instances. If this was done in the case reported, this consultant would recommend no further treatment at this time. Most salivary gland tumors are moderately radiation-resistant, and it is not advisable to use x-ray therapy as a routine postoperative measure.

DEGENERATION OF THE TEETH

To the Editor:—*Is there any beneficial effect of the combined use of estrogens and androgens for treatment of degeneration of teeth? Mainly, is such treatment as effective as in osteoporosis of senility in the laying down of new bony matrix?*

Murray Russell, M.D., Garden Grove, Calif.

Answer.—It is assumed that "degeneration of teeth" refers to the loss of supporting alveolar bone as is seen in periodontal disease. If this is so, there is no indication in the literature or elsewhere that the use of estrogens and androgens would be of any value in restoring the destroyed supporting bone.

IODINE AND ACNE

To the Editor:—*In a high school health textbook, a footnote says, "Teenagers who have pimples should avoid iodized salt." Is there a medical basis for such a statement?*

Fred H. Wiechman, M.D., Jacksonville, Fla.

Answer.—Most dermatologists agree that there is a medical basis for this statement. Iodine in itself may cause an acneiform eruption. It is recognized that often the ingestion of iodine results in the exacerbation of a preexisting acne vulgaris. This is believed to be due to the excretion of the iodine through the skin with irritation of the pilosebaceous apparatus, a structure which might be termed the "shock-organ" in acne vulgaris. Iodine may enter the system from sources other than iodized salt. Some of the more common ones include fish and sea foods, medication taken internally or applied locally, vegetables grown in a soil with a high iodine content, or drinking water. Many patients' acne gets worse when they move to the sea coast because of the latter source of iodine. Bromine has the same deleterious effect on acne as does iodine, but the other halogens, chlorine and fluorine, do not cause an aggravation of this condition.

TREATMENT OF MILIA

To the Editor:—*An 18-year-old girl has what she thinks is acne. Actually, she has a good many milia (whiteheads) rather than comedones. These were small and primarily over the malar region. In addition, she had a few scaly-appearing seborrheic areas. Her face was rather oily. She had no dandruff particularly. What medicament would be effective in the treatment of these whitish small papules? Incidentally, these are rather firm and do not secrete fluid of any kind. Would dermal abrasion be justified?*

M.D., Alabama.

Answer.—Planing frequently causes the formation of milia itself, so this treatment would not be indicated in this patient. Dermal abrasion does not extend sufficiently deep to remove the adnexa of the skin. Deeper planing may result in scarring that would be more objectionable than the "whiteheads" and more difficult to eradicate. The best treatment for this condition is a tedious one, involving needling of each milium under sterile technique and expressing the contents carefully and completely with a comedone extractor. Treatment of the seborrheic areas with a 3% sulfur precipitate and 3% salicylic acid cream would be indicated also.

RECURRENT INFECTIOUS MONONUCLEOSIS

To the Editor:—*Have there been any reported cases of infectious mononucleosis occurring a second time—not as a recurrence of the initial illness—in the same person? Could infectious mononucleosis be followed or accompanied by infectious hepatitis?*

M.D., Illinois.

Answer.—The degree of immunity conferred by an attack of infectious mononucleosis is undetermined. However, even in communicable diseases known to produce a strong immunity after an attack, occasionally second attacks do occur in certain individuals. The mechanisms of bacterial or viral synergism or interference are not too well known, but the coexistence of two infectious diseases is, in general, a rare event. Liver involvement, with or without jaundice, occurs in a high proportion of patients with infectious mononucleosis, as shown by abnormal results in liver function tests. The possibility of confusing infectious mononucleosis with infectious hepatitis is especially likely in view of the lymphocytosis which frequently accompanies the latter disease.

ASTHMA AND SEDIMENTATION RATE

To the Editor:—*A patient has an erythrocyte sedimentation rate of 30 mm. per hour. He has had bronchial asthma and some bronchiectasis for several years. As far as can be determined, there is nothing to indicate an infection anywhere. Could the presence of asthma and/or bronchiectasis account for the increased sedimentation rate?*

Clyde K. Walter, M.D., Canfield, Ohio.

Answer.—On the basis of the facts presented, all that can be said is that the erythrocyte sedimentation rate of 30 mm. per hour (assuming that the test was performed by the Westergren technique) could be accounted for by the diseases mentioned, although the moderate elevation may be caused by some other process. Chronic, nonextensive bronchiectasis and asthma as a rule do not cause increases in the sedimentation rate, but during exacerbations the rate frequently increases.

IMMUNOLOGY OF SMALLPOX VACCINATION

To the Editor:—*What is the mechanism of protective action of vaccination against smallpox? Is it a system of antibodies or some other effect of the cowpox vaccine?* *M.D., Illinois.*

Answer.—The relationship between the viruses of smallpox, alastrim, vaccinia, cowpox, and ectromelia is a close one, and a great deal of cross protection, sometimes complete, occurs between them. No difference is detectable between smallpox and alastrim. Vaccinia virus closely resembles smallpox virus, while cowpox virus, on the other hand, is more closely related to the virus of ectromelia. It seems probable that the present strains of vaccinia virus are derived from smallpox rather than from cowpox. The immunological mechanisms of protection are the usual ones, consisting of neutralizing virucidal antibodies and agglutinins, precipitins, and complement-fixing and antihemagglutinating bodies.

CHLOROPHYLLINS

To the Editor:—*Are chlorophyllins harmful in any way?* *M.D., Alabama.*

Answer.—Chlorophyllins are water-soluble derivatives of chlorophyll, the green coloring matter of plants. They are prepared commercially by saponification of a source of chlorophyll, such as alfalfa, and by replacement of the magnesium present in the original chlorophyll molecule by another metal, usually copper, to give a more stable compound. The chlorophyllin used in deodorant preparations and described as potassium sodium copper chlorophyllin apparently is not a pure product. The question has been raised as to whether the copper present in this preparation is a potential source of toxicity. However, the copper in the complex is so firmly bound to the chlorophyll moiety that metallic poisoning would not occur unless an excess of copper were present.

PREGNANCY AND BREAST CARCINOMA

To the Editor:—*Are further pregnancies contraindicated in a woman who has had carcinoma of the breast, duct type, for which radical mastectomy of the left breast and simple mastectomy of the right breast were done?*

R. A. Bussabarger, M.D., Raymond, Wash.

Answer.—There are some surgeons and roentgenologists who believe it is dangerous for a woman who has had an operation for carcinoma of the breast to become pregnant again. The reason for this is that in several instances pregnancy and/or lactation seemed to have induced recurrences. However, this consultant believes that, if this patient remains well for three years without evidence of recurrence or metastases, she may bear more children.

TYPHOID BOOSTER IMMUNIZATIONS

To the Editor:—*How often is an intradermal typhoid-paratyphoid booster dose needed after an initial series of three 0.1-cc. injections at weekly intervals?*

W. M. Fowlkes Jr., M.D., Wendell, N. C.

Answer.—An intradermally given booster dose every three years is sufficient under "normal" circumstances. However, persons exposed to heavy risks of infection, i. e., living in areas where typhoid is endemic, should get a booster injection every year.

SMOKING AND VITAMINS

To the Editor:—*What is the effect on vitamin metabolism, especially that of the vitamin B complex group and vitamin C, in the human body in an individual who smokes and inhales 20-40 cigarettes a day?*

W. Forrester Maley, M.D., Chicago.

Answer.—This consultant is unaware of any evidence indicating that cigarette smoking has an adverse effect on the body's ability to utilize vitamins.

SUBJECT INDEX

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; " abstracts; the asterisk (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word with the following exceptions: Foundations, Lectures, Pictures, and Prizes, under "F," "L," "M," and "P" respectively. "Book Reviews," "Deaths," "Medicolegal Abstracts" and ." are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For the author index see page 48.

FOR CONTROL OF MENORRHAGIA

ENOVID®

Prolonged or excessive menstrual flow of functional origin can be treated both therapeutically and prophylactically with Enovid.

The supportive action of two tablets of Enovid on the endometrium usually checks abnormal bleeding within six to twelve hours. A daily dosage of one or two tablets is then continued through the intermenstrual interval until day 25 of the cycle. The patient will menstruate approximately three days after discontinuance of therapy.

She is again treated with similar doses from day 5 to day 25 for two or three additional consecutive cycles.

A similar regimen is employed if the patient is seen during the intermenstrual interval. Even though no bleeding is present a dosage of one or two tablets daily is administered until day 25. Therapy is resumed from day 5 to day 25 for two or three successive cycles.

Each tablet of 10 mg. contains 9.85 mg. of norethynodrel, a new synthetic steroid, and 0.15 mg. of ethynylestradiol 3-methyl ether. G. D. Searle & Co., Chicago 80, Illinois.

ENOVID Oral Synthetic Endometropin
(brand of norethynodrel with ethynylestradiol 3-methyl ether)

SEARLE | *Research in the Service of Medicine*

BREACH THE INFLAMMATORY WALL

ACCELERATE TISSUE REPAIR

The wall of leukocytes and fibrin that surrounds every site of inflammation breaks down when Parenzyme is administered *systemically* and/or *topically*.
Parenzyme depolymerizes macromolecules trapped in the capillary wall and connective tissue—permits access of anti-infective agents, accelerates tissue repair, resolves inflammation and edema.

PARENZYME® AQUEOUS
PARENZYME®-B *(buccal tablet)*
PARENZYME® OINTMENT

Parenzyme *Aqueous* — sterile multiple-dose vials containing lyophilized trypsin, 25 mg. plus 5 ml. of aqueous diluent. **Parenzyme-*B*** — buccal tablet containing 5 mg. trypsin. **Parenzyme *Ointment*:** containing 2 mg. crystalline trypsin, 6 mg. crystalline chymotrypsin and 2 mg. 9-aminoacridine hydrochloride in a specially prepared water-soluble base.

PAIN

Zactirin®

Ethoheptazine Citrate with Acetylsalicylic Acid, Wyeth

for everyday pain control . . .

for your many patients requiring potent analgesia but not an injected narcotic

Proved by extensive evaluation[1,2,3] in 1998 patients in diverse areas of medicine and surgery, including:

arthritis, bursitis, early metastatic carcinoma, fibrositis, grippe, herpes zoster, ligamental strain, low back pain, menstrual pain, myalgia, myositis, neuritis, pleurisy, postoperative pain, postpartum pain, sciatica, trauma, dental pain

- *exclusive Wyeth non-narcotic analgesic plus anti-inflammatory action*
- *prompt, potent action—as potent as codeine*
- *documented effectiveness and safety[1,2,3]*

Supplied: Tablets, bottles of 48. Each tablet contains 75 mg. of ethoheptazine citrate and 325 mg. (5 grains) of acetylsalicylic acid.

Wyeth®

new antibiotic, misuse of, [Mann] 814—C
KANTREX: See Kanamycin
KELOIDS
treatment, oral, [Kelly] 2073—ab
KERATITIS
interstitial, nonsyphilitic, and bilateral deafness (Cogan's syndrome) with cardiovascular disease, [Eisenstein] 108—ab
KERNICTERUS
in premature infants associated with low bilirubin level in plasma, [Harris] 461—ab
17-KETOSTEROIDS
urinary excretion in leishmaniasis, India, 209
KIDNEYS
artificial, in control of accidental poisoning, [Cann & others] *717
artificial, Kolff twin coil, [Holmes] 1414—ab
biopsy, France, 1797
biopsy specimens from patients with hypertension; histology, [Sommers] 970—ab
calculi (calcium), excretion of calcium and inorganic phosphate in, [Hodgkinson] 1820—ab
calculi complicating rehabilitation of respirator patient, [Neu] *1610
cystic disease in infants, [Hooper] 466—ab
disease, chronic, in children; correlate clinical findings with morphology, [Vernier] 1942—ab
disease, low-sodium diets in, (Council report) [Danowski] *1886
disease, nephrectomy in juvenile hypertension with, [Welch] 463—ab
disease, nephrolithiasis in children, diagnosis, [Diligenskaya] 341—ab
disease (nephrosis) in children and adults, prolonged intermittent steroid therapy for, [Lange & others] *377
disease (nephrotic syndrome) complicating mercurial diuretic therapy, [Riddle] 126—ab
disease (nephrotic syndrome) in man 38, treatment, 1956
disease (nephrotic syndrome, reversible) with congestive heart failure, [Burack] 2298—ab
foreign bodies in, needle within calyces, [Naulleau] 344—ab
function in patients recuperated from severe hypertension with treatment, [Caeiro] 819—ab
function, preserve during partial nephrectomy, rubber band tourniquet for hemostasis, [Goodwin & Thelen] *179
function test in leprosy, India, 1797
function tests abnormal in Coxsackie B virus infection, [Utz & Shelokov] *264
Goldblatt, nephrogenic hypertension after operative trauma to renal artery, [McDonald] 451—ab
Inflammation: See Nephritis
insufficiency (acute failure) and generalized pain, (Diagnostic Problems) [Kushner & Szanto] *1778
insufficiency (acute failure), atypical heat stroke with, [Baxter] 109—ab
insufficiency after delivery, prognosis, [Thaysen] 1275—ab
insufficiency (chronic failure), signs and symptoms, [Effersøe] 214—ab
nephrogenous polycythemia, [Forssell] 1821—ab
papillary necrosis, [Hultengren] 961—ab
papillary necrosis, roentgen diagnosis and formation of calculi, [Lagergren] 130—ab
primary renal hypokalemia vs. primary aldosteronism, [Alsted] 1578—ab
renal hypertension as consequence of increased arterial pressure, study in rats, [Masson] 2076—ab
rupture, management of severely injured patient, [Schulte] *2094
surgery, subcapsular nephrectomy, [Kittredge & Fridge] *758
transplantation between 7 pairs of identical twins, [Murray] 2190—ab
KLINEFELTER SYNDROME
chromatin-positive, true; relation to feeblemindedness, [Prader] 2193—ab
KNEE
arthrosis of, Sweden, 2294
compression in arthrodesis, comparative methods of fusion, [Stewart] 328—ab

KOPLIK, HENRY (1858-1927)
centennial exhibit, N. Y., 1911
KRAUROSIS
leukoplakia syndrome, vulvar, topical androgens for, [Richardson] 2312—ab
KRUSEN, FRANK HAMMOND, A. M. A. Distinguished Service award to, 53
KWASHIORKOR
dried skimmed milks and, [Pretorius] 223—ab
4 cases from Louisiana, [Henington] 1277—ab
KYASANUR Forest disease, India, 804
KYNEX: See [illegible]
Acetyl: See [illegible]
KYPHOSCOLI

L

LSD: See *d*-Lysergic Acid Diethylamide
LABELS
of chemical products, draft model bill to require warning of hazardous ingredients, 1062
LABOR
acute renal insufficiency originated after, prognosis, [Thaysen] 1275—ab
after previous cesarean section, India, 2042
cesarean section for cephalopelvic disproportion after previous vaginal deliveries, [Davila] 2069—ab
midline episiotomy, Brazil, 88
premature, associated with malaria, United Kingdom, 1927
premature, USPHS grant for study of, Pa., 701
promethazine in, 2½ year survey, [Carroll & Moir] *2218
pulmonary hyaline membrane contamination of lungs by fluid of birth canal, studies in rabbits, [Snyder] 120—ab
rupture of normal spleen in infant during, [Hottinger] 461—ab
type of, evaluation of newborn infant, [Apgar & others] *1985
LABOR (industrial): See Industrial Accidents; Industrial Diseases; etc.
LACERATIONS
in boxers, relation to renal injury, [Kleiman] *1633
LACRIMATION
tear gas exposure, treatment, 1167
LACTATION
deodorants relation to supply of milk, 1297
precordial murmurs during, [Hurst] 1939—ab
Vanderbilt study of maternal and infant nutrition, (Council article) [McGanity & others] *2138
LACTIC ACID
bacilli in cow's milk, source of, 981
LAL, GOBIND BEHARI A. M. A. distinguished service citation to, 53
LAMBLIASIS: See Giardiasis
LAPAROSCOPY
value in ascitic syndromes presenting diagnostic difficulties, [Girard] 2189—ab
LAPAROTOMY: See Abdomen surgery
LARGACTIL: See Chlorpromazine
LARVA MIGRANS
ancylostomiasis braziliensis, [van Zeben] 833—ab
LARYNGITIS
functional, 1733
LARYNX
minor sequelae after endotracheal intubation, [Wolfson] 1417—ab
obstruction, prednisone treatment, India, 707
stridor in rheumatoid arthritis, [Darke] 123—ab
LATEX
fixation test, slide, in diagnosis of rheumatoid arthritis, [Singer & Plotz] *180
LAWS AND LEGISLATION
